Influence of Bending–Twisting coupling on compression buckling strength.

PRESENTATION CONTENTS

- Stacking sequence listings are derived for Bending-Twisting coupled laminates with up to 21 plies.
- The common design rule of balanced and symmetric stacking sequences will be shown to predominantly give rise to Bending-Twisting coupling; all exceptions are presented in Journal of Aircraft, 2009, 46 (4) pp. 1114-25.
- The symmetry rule will be shown to be a constraint that serves only to restrict the number of possible configurations to a very small proportion of the total design space.
- Dimensionless parameters will be presented from which the laminate properties are readily calculated.
- Expressions relating the dimensionless parameters to the well-known lamination parameters are also given, together with graphical representations of the design space.
- Finally, bounds on buckling performance under compression will be presented with specific reference to the lamination parameter design space.
CHARACTERIZATION

Composite laminate materials are typically characterized in terms of their response to mechanical or thermal loading, which is generally associated with a description of the coupling behavior, described by the ABD relation:

\[
\begin{align*}
\begin{bmatrix}
N_x \\
N_y \\
N_{xy}
\end{bmatrix} &=
\begin{bmatrix}
A_{11} & A_{12} & A_{16} \\
A_{22} & A_{26} & A_{66}
\end{bmatrix}
\begin{bmatrix}
\varepsilon_x \\
\varepsilon_y \\
\gamma_{xy}
\end{bmatrix} +
\begin{bmatrix}
B_{11} & B_{12} & B_{16} \\
B_{22} & B_{26} & B_{66}
\end{bmatrix}
\begin{bmatrix}
\kappa_x \\
\kappa_y \\
\kappa_{xy}
\end{bmatrix}
\end{align*}
\]

Couplings generally exist between:

- in-plane (extension or membrane) and out-of-plane (bending or flexure) actions, when \(B_{ij} \neq 0\),
- shear and extension, when \(A_{16} = A_{26} \neq 0\), and
- bending and twisting, when \(D_{16} = D_{26} \neq 0\).
Influence of Bending–Twisting coupling on compression buckling strength.

*Balanced and symmetric stacking sequences*, may or may not possess *Bending-Twisting* coupling, and are therefore characterized, respectively, by the designations:

\[
A_S B_0 D_F \text{ or } A_S B_0 D_S
\]

signifying, in both cases, that the elements of the extensional stiffness matrix \((A)\) are *Simple* or orthotropic in nature, i.e.:

\[
\begin{bmatrix}
A_{11} & A_{12} & 0 \\
A_{22} & 0 \\
\text{Sym.} & A_{66}
\end{bmatrix}
\]

the (bending-extension) coupling matrix \((B)\) is null, whilst all elements of the bending stiffness matrix \((D)\) are either *Finite*, i.e.:

\[
\begin{bmatrix}
D_{11} & D_{12} & D_{16} \\
D_{22} & D_{26} \\
\text{Sym.} & D_{66}
\end{bmatrix}
\]

or of the same *Simple* or orthotropic form as the extensional stiffness matrix.
Table 1 – Unrestrained thermal (contraction) response of square, initially flat, composite laminates. Stacking sequence configurations containing angle- and cross-ply sub-sequences are a representative sample from the minimum ply number grouping of each class of laminate. Note that cross-ply laminates with stacking sequences \([\Omega/\Omega]_T\) also represent the minimum ply number grouping for designation \(A_S B_0 D_S\), but such configurations are not considered in this study.

ARRANGEMENT AND FORM OF STACKING SEQUENCE DATA

Stacking sequences are characterized by sub-sequence symmetries using a double prefix notation:

the first character relates to the form of the angle-ply sub-sequence and

the second character to the cross-ply sub-sequence.

The double prefix contains combinations of the following characters:

- A to indicate Anti-symmetric form;
- N for Non-symmetric; and
- S for Symmetric.

Additionally, for cross-ply sub-sequence only,

- C is used to indicate Cross-symmetric form.

To avoid the trivial solution of a stacking sequences with cross plies only, the first ply in every sequence is an angle-ply (+).
Fully uncoupled laminates have the following forms of sub-sequence symmetries:

DEVELOPMENT OF NON-DIMENSIONAL PARAMETERS

The derivation of non-dimensional bending stiffness parameters is readily demonstrated for the 9-ply NN 5 laminate, with stacking sequence \([+/-/O_2/+/-/O/+]_T\), where the bending stiffness terms,

\[ D_{ij} = \sum_{k=1}^{n} Q'_{ij}(z_k^3 - z_{k-1}^3)/3 \]

may be written in sequence order as:

\[
D_{ij} = \{ Q'_{ij+}((-7t/2)^3 - (-9t/2)^3) + Q'_{ij-}((-5t/2)^3 - (-7t/2)^3) + Q'_{ij\circ} (-3t/2)^3 \\
- (-5t/2)^3) + Q'_{ij\circ}((-t/2)^3 - (-3t/2)^3) + Q'_{ij+}((t/2)^3 - (-t/2)^3) + Q'_{ij-}((3t/2)^3 \\
- (t/2)^3) + Q'_{ij-}((5t/2)^3 - (3t/2)^3) + Q'_{ij\circ}((7t/2)^3 - (5t/2)^3) + Q'_{ij+}((9t/2)^3 \\
- (7t/2)^3)\}/3
\]

where subscripts \(i,j = 1, 2, 6\).

The bending stiffness contributions from the different ply orientations are:

- \(D_{ij+} = 96.75t^3/3 \times Q'_{ij+} = \zeta_{+} t^3/12 \times Q'_{ij+}\), \(\zeta_{+} = 387\)
- \(D_{ij-} = 42.75t^3/3 \times Q'_{ij-} = \zeta_{-} t^3/12 \times Q'_{ij-}\), \(\zeta_{-} = 171\)
- \(D_{ij\circ} = 42.75t^3/3 \times Q'_{ij\circ} = \zeta_{\circ} t^3/12 \times Q'_{ij\circ}\), \(\zeta_{\circ} = 171\)

\(\zeta_{+} + \zeta_{-} + \zeta_{\circ} = n^3 = 729\)
CALCULATION OF THE LAMINATE BENDING STIFFNESS

Calculation of the bending \( (D) \) stiffness matrix, follows from the dimensionless parameters using:

\[
D_{ij} = \{ \zeta_{+} Q_{ij}^{+} + \zeta_{-} Q_{ij}^{-} + \zeta_{o} Q_{ij}^{o} + \zeta_{\bullet} Q_{ij}^{\bullet} \} \times r^3/12
\]  

(1)

The transformed reduced stiffness terms in Eqs. (1) are given by:

\[
Q'_{11} = Q_{11} \cos^4 \theta + 2(Q_{12} + 2Q_{66}) \cos^2 \theta \sin^2 \theta + Q_{22} \sin^4 \theta
\]

\[
Q'_{12} = Q'_{21} = (Q_{11} + Q_{22} - 4Q_{66}) \cos^2 \theta \sin^2 \theta + Q_{12}(\cos^4 \theta + \sin^4 \theta)
\]

\[
Q'_{16} = Q'_{61} = ((Q_{11} - Q_{12} - 2Q_{66}) \cos^2 \theta + (Q_{12} - Q_{22} + 2Q_{66}) \sin^2 \theta) \cos \theta \sin \theta
\]

\[
Q'_{22} = Q_{11} \sin^4 \theta + 2(Q_{12} + 2Q_{66}) \cos^2 \theta \sin^2 \theta + Q_{22} \cos^4 \theta
\]

\[
Q'_{26} = Q'_{62} = ((Q_{11} - Q_{12} - 2Q_{66}) \sin^2 \theta + (Q_{12} - Q_{22} + 2Q_{66}) \cos^2 \theta) \cos \theta \sin \theta
\]

\[
Q'_{66} = (Q_{11} + Q_{22} - 2Q_{12} - 2Q_{66}) \cos^2 \theta \sin^2 \theta + Q_{66}(\cos^4 \theta + \sin^4 \theta)
\]

(2)

and the reduced stiffness terms by:

\[
Q_{11} = E_1/(1 - \nu_{12} \nu_{21}) \quad Q_{12} = \nu_{12} E_2/(1 - \nu_{12} \nu_{21}) \quad Q_{22} = E_2/(1 - \nu_{12} \nu_{21}) \quad Q_{66} = G_{12}
\]

(3)
LAMINATION PARAMETERS

For optimum design of laminates with angle- and cross-ply orientations, lamination parameters are often preferred, since these allow the stiffness terms to be expressed as linear design variables.

\[
\begin{align*}
\xi_9 &= \xi_1^D = \{\zeta_1 \cos(2\theta_+) + \zeta_2 \cos(2\theta_-) + \zeta_3 \cos(2\theta_\circ) + \zeta_4 \cos(2\theta_\bullet)/n^3 \\
\xi_{10} &= \xi_2^D = \{\zeta_5 \cos(4\theta_+) + \zeta_6 \cos(4\theta_-) + \zeta_7 \cos(4\theta_\circ) + \zeta_8 \cos(4\theta_\bullet)/n^3 \\
\xi_{11} &= \xi_3^D = \{\zeta_9 \sin(2\theta_+) + \zeta_{10} \sin(2\theta_-) + \zeta_{11} \sin(2\theta_\circ) + \zeta_{12} \sin(2\theta_\bullet)/n^3 \\
\xi_{12} &= \xi_4^D = \{\zeta_5 \sin(4\theta_+) + \zeta_{10} \sin(4\theta_-) + \zeta_{11} \sin(4\theta_\circ) + \zeta_{12} \sin(4\theta_\bullet)/n^3
\end{align*}
\]

Calculation of the bending \((D)\) stiffness matrix, follows from the dimensionless parameters using:

\[
\begin{align*}
D_{11} &= \{U_1 + \xi_9 U_2 + \xi_{10} U_3\} \times H^3/12 \\
D_{12} &= D_{21} = \{U_4 - \xi_{10} U_3\} \times H^3/12 \\
D_{16} &= D_{61} = \{\xi_{11} U_2/2 + \xi_{12} U_3\} \times H^3/12 \\
D_{22} &= \{U_1 - \xi_9 U_2 + \xi_{10} U_3\} \times H^3/12 \\
D_{26} &= D_{62} = \{\xi_{11} U_2/2 - \xi_{12} U_3\} \times H^3/12 \\
D_{66} &= \{-\xi_{10} U_3 + U_5\} \times H^3/12
\end{align*}
\]

\(H (= n \times t)\) is the laminate thickness.

\[
\begin{align*}
U_1 &= \{3Q_{11} + 3Q_{22} + 2Q_{12} + 4Q_{66}/8 \\
U_2 &= \{Q_{11} - Q_{22}\}/2 \\
U_3 &= \{Q_{11} + Q_{22} - 2Q_{12} - 4Q_{66}\}/8 \\
U_4 &= \{Q_{11} + Q_{22} + 6Q_{12} - 4Q_{66}\}/8 \\
U_5 &= \{Q_{11} + Q_{22} - 2Q_{12} + 4Q_{66}\}/8
\end{align*}
\]
Influence of Bending–Twisting coupling on compression buckling strength.

Figure 7 – Bending lamination parameter ($\xi_9$, $\xi_{10}$, $\xi_{11}$) design space for symmetric (SS) laminates with up to 18 plies, representing 23,470 configurations. Note that $\xi_{12} = 0$ for $\theta = \pm45^\circ$. 
BUCKLING STRENGTH ASSESSMENTS

Numerous closed form solutions have been proposed in the literature. The most recent being:

\[ k_{x,\infty} = 2(1 - 4\delta\gamma - 3\delta^4 + 2\delta^2\beta)^{1/2} + 2(\beta - 3\delta^2) \]

However, results for the fully uncoupled laminate (\(\gamma = \delta = 0\)) do not match the relative buckling load, \(N_{x,\infty}\) (with half-wavelength \(\lambda\)), across the lamination parameter design space due to normalization with respect to \((D_{11}D_{22})^{1/2}\), i.e.:

\[ k_{x,\infty} = N_x b^2 / \pi^2 (D_{11}D_{22})^{1/2} \text{ with } N_{x,\infty} = \pi^2 \left[ D_{11} \left( \frac{1}{\lambda} \right)^2 + 2(D_{12} + 2D_{66}) \frac{1}{b^2} + D_{22} \left( \frac{1}{b^4} \right) \lambda^2 \right] \]
Influence of Bending–Twisting coupling on compression buckling strength.

An alternative assessment of the buckling strength between fully uncoupled (or Simple) laminates and Bending-Twisting coupled laminates is now considered. Here, a mapping to the lamination parameter design space is developed.

An 18-ply quasi-homogeneous laminate configuration \((A_S B_0 D_S)\) was chosen to check for convergence of the buckling strength predictions of an exact infinite strip method, VICONOPT\(^1\), since it represents the simplest form of laminate, i.e.:

\[
D_{ij} = A_{ij}H^2/12
\]  

(7)

Additionally, this laminate becomes a fully isotropic \((\pi/3)\) laminate when angle plies \((+/-)\) are changed from \(+45/-45\) to \(+60/-60\). This is used as a datum case.

\[
[+/---]/[O/O/O/+/+/O/--+/--/--/O/O/+]_T \quad (A_S B_0 D_S), (A_I B_0 D_I)
\]

Buckling factor results have been normalised against \(D_{iso}\), representing the equivalent isotropic composite bending stiffness, where

\[
D_{iso} = E_{iso}H^3/(1 - \nu_{iso}^2) = U_1 H^3/12
\]  

(8)

\[
E_{iso} = 2(1 + \nu_{iso})G_{iso} = U_1(1 - \nu_{iso}^2)
\]  

(9)

\[
\nu_{iso} = U_2/U_1
\]  

(10)

Figure 1 – Compression buckling contours, \( k_x = N_x b^2/\pi^2 D_{iso} \), for fully uncoupled laminates, i.e. \( \xi_{11} = 0 \).

The closed form buckling solution, representing an infinitely long, simply supported plate, and from which the contours are subsequently plotted, can be derived from 15 lamination parameter points, giving:

\[
k_{x,\infty} = 4.000 - 1.049 \xi_{10} - 1.217 \xi_9^2 + 0.340 \xi_{10} \xi_9^2 - 0.360 \xi_9^4 - 0.340 \xi_{10}^2 \xi_9^2
\]
Influence of Bending–Twisting coupling on compression buckling strength.

Figure 2 – Compression buckling factor contours, $k_x$ ($= N_x b^2/\pi^2 D_{iso}$), for $\xi_{11} = 0.5$, representing Bending-Twisting coupled laminates, demonstrating increasing asymmetry. When $\xi_{11} = 1.0$, the design space degenerates to a single point with $k_x = 2.19$.

For $\xi_{11} = 0.5$, the new closed form buckling solution for the infinitely long plate can be stated as:

$$k_{x, ortho, \infty} = 3.374 - 0.329 \xi_9 - 1.06 \xi_{10} - 1.742 \xi_9^2 - 0.012 \xi_{10}^2 + 0.145 \xi_{10} \xi_9 - 0.598 \xi_9^3 - 0.001 \xi_{10}^3 - 0.014 \xi_{10}^2 \xi_9 + 0.671 \xi_{10} \xi_9^2 - 1.456 \xi_9^4 - 0.003 \xi_{10}^3 \xi_9 - 0.083 \xi_{10}^2 \xi_9^2 - 0.008 \xi_{10} \xi_9^3$$
Figure 3 – Compression buckling factor curves for:

(a) quasi-homogeneous, quasi-isotropic laminates with $(\xi_9, \xi_{10}) = (0,0)$ and $0 \leq \xi_{11} \leq 0.5$ and;

(b) angle-ply laminates with $(\xi_9, \xi_{10}) = (0,-1)$ and $0.0 \leq \xi_{11} \leq 1.0$.

Asymptotes represent $k_{x,\infty}$ for the infinitely long plate, and reveal bounds on buckling strength reductions of 16% for the quasi-homogeneous, quasi-isotropic laminates and 57% for angle-ply laminates.
Influence of Bending–Twisting coupling on compression buckling strength.

Results for isotropic skew plates – mode shape analogy.

FIG. 6. Case 1-2 Design Curves for $\alpha = (a) \, 15^\circ$, (b) $30^\circ$, (c) $45^\circ$ with Skew-Transverse Edges Elastically Restrained against Rotation and Longitudinal Edges Simply Supported. Discrete Results [Mizusawa and Kajita (1986)] shown ($\kappa = 0, 0.1, 1, 2, 5, 10, 100$ and $\infty$) for Comparison.
CONSIDERATIONS FOR FML

Initial buckling strength.

Material properties of FML are essentially isotropic. \([\text{Al}/+45/-45/\text{Al}/-45/+45/\text{Al}]_T\) gives the highest magnitude of Bending-Twisting coupling, but the buckling curves have no diminishing cusps, as seen previously in the Uni-Directional (UD) CFRP designs. The buckling strength of this design increased in comparison to equivalent design with ‘isotropic’ fibre layers, since \(\xi_{10} < 0\); see trends in buckling factor contours in Figs. (1) and (2).

Delamination buckling

Favourable designs were found to be dominated by anti-symmetric UD laminate designs. The use of woven cloth or Non-Crimp Fabric (NCF) designs using thin ply technologies may improve isotropic characteristics and potentially improve damage tolerance.

Influence of Bending–Twisting coupling on compression buckling strength.

**Woven Cloth Material.**

Application to FML using Aluminium and Boron- or Carbon-Fibre epoxy woven cloth (TeXtreme™) layers, involving thin ply laminate technology with areal weights of 50g/m², compared to standard materials with 250g/m², allows the possibility of designing isotropic layers, e.g.

$$[\alpha/\beta/\alpha/\beta_3/\alpha_3/\beta/\alpha/\beta]_T$$

with $$\alpha = \beta + \pi/4$$, possessing similar moduli to Aluminium, and within the thickness constraints found in standard FML, such as Glare, e.g.:

$$[\text{Al./}\alpha/\beta/\alpha/\beta_3/\alpha_3/\beta/\alpha/\beta/\text{Al.}/\alpha/\beta/\alpha/\beta_3/\alpha_3/\beta/\alpha/\beta/\text{Al.}]_T.$$  

Titanium may be required to avoid galvanic corrosion between Aluminium and Carbon-Fibre material.

**Non-Crimp Fabric (C-Ply)**

The four design freedoms associated with the stacking sequences for standard UD laminate manufacture, with ply orientations 0, 90 and ±45°, are increased to eight using 0/45 and 0/-45 bi-angle NCF: by flipping (-45/0 and 45/0), rotating (90/-45 and 90/45) or both (45/90 and -45/90). The underlining helps to differentiate between 0/45 and 0/-45 plies.

A comparable isotropic sub-laminate to the TeXtreme design is given by:

$$[135/90/0/45/0/45/90/45/-45/0/135/90/135/90/45/90/0/-45/0/45/0/45/135/90]_T$$
Addendum: Matching of Stiffness and Thermal properties in FML

Table 2 - Engineering constants, thermal expansion coefficients and specific gravity of typical unidirectional composites together with equivalent Isotropic laminate properties.

CONCLUSIONS

- Definitive listings of $Bending$-$Twisting$ coupled laminates demonstrate that the vast majority of the stacking sequences are non-symmetric.

- Symmetric laminates with up to 18 plies occupy less than 7% of the total design space for $Bending$-$Twisting$ coupled laminates.

- Interrogation of these feasible design spaces has facilitated the calculation of bounds on the buckling strength of infinitely long simply supported plates.

- Buckling strength comparisons for infinitely long laminated plates have revealed bounds on buckling strength reductions between fully uncoupled and $Bending$-$Twisting$ coupled laminates of 16% for the quasi-homogeneous, quasi-isotropic laminates and 57% for angle-ply laminates.

- FML designs possess buckling behaviour consistent with the equivalent isotropic laminate, despite the presence of $Bending$-$Twisting$ coupling in the fibre reinforcement.
  
  o The potential for improvements in delamination buckling strength (i.e., compression strength after impact) remains to be explored....
