On the fly multi-modal observation of ligand synthesis and complexation of Cu complexes in flow with ‘benchtop’ NMR and mass spectrometry

Luzian Porwol, Alon Henson, Philip J. Kitson, De-Liang Long and Leroy Cronin*

Exploring complex chemical systems requires reproducible and controllable ways to access non-equilibrium conditions. Herein we present a programmable flow system that can do both ligand synthesis and complexation on the fly, and the conditions of the reaction can be monitored using two simultaneous techniques, namely NMR and mass spectrometry. By using this approach we not only monitored the formation of unknown complexes, followed by crystallization that resulted in the characterisation of their structures giving 4 new compounds which can be formulated as: Cu$_2$(L$^1$)$_2$($\mu$-CO$_3$)$_2$(BF$_4$)$_2$ (2); [Cu(L$^1$)$_2$($\mu$-CO$_3$)][PF$_6$]$_2$(OH)$_2$ (3) [Cu(L$^2$)$_2$][BF$_4$]$_2$ (4) and [Cu(L$^3$)$_2$](BF$_4$)$_2$·CH$_3$CN (5).

Introduction

Complex molecular architectures can often form through multi-component coordination chemistry, but often this chemistry is restricted to one pot reactions. Under most conditions the mechanism of the underlying process of self-assembly is well known being based on the rules of acceptor-donor interactions and are therefore understood and often predictable. However the principle of pre-organisation and self-sorting, although well established to control the outcome of complex molecular architectures, do not apply under non-equilibrium conditions. This means that there is a pressing need to combine the design of coordinating ligands, via coordination programming, with non-equilibrium dynamics to explore the reproducible formation of more complex and structurally diverse architectures. This has not been possible since the approach requires real-time observation of the reaction process. Success could allow the ‘digitalisation’ of chemical discovery and synthesis. Indeed, this digitalisation is long overdue with respect to the development of methods that allow synthesis to be followed more closely, gaining a deeper insight in experiments to be performed more reliably without extensive investment of time and money for so called ‘routine’ literature procedures.

Herein we realise this idea by automating and monitoring the self-assembly of coordination complexes under non-equilibrium conditions. A purpose built flow system allows for automation and live control of multi-step reactions (see Figure 1) under a semi-inert atmospheric reaction conditions. This platform not only permits us to follow the reaction progress in real-time, but also to optimise, as well as reliably reproduce, the self-assembly process via in-line analysis using a bench top NMR spectrometer and a portable MS. To explore this concept, we initially chose to study a simple ligand-complex model system as a proof of concept that we can detect, follow, understand and processes for new and complex coordination architectures. This study lead to the identification of an intermediate species [Cu(i)(L$^1$)$_2$] (1) – which is not possible to isolate or observe using classical synthetic procedures – important for the self-assembly of two new complexes isolated after crystallization: [Cu$_2$(L$^1$)$_2$($\mu$-CO$_3$)][BF$_4$]$_2$ (2); [Cu$_2$(L$^3$)$_2$($\mu$-CO$_3$)][PF$_6$]$_2$(OH)$_2$ (3). It was also possible to identify a binuclear Cu-complex [Cu$_2$(L$^2$)$_2$][BF$_4$]$_2$ (4) and [Cu(L$^3$)$_2$](BF$_4$)$_2$·CH$_3$CN (5) in situ.

Fig. 1 Schematic representation of the digital-programmable-flow-platform to perform ligand-complex synthesis in an automated way. The syringe pumps are computer controlled to deliver the chosen reagents in a well synchronized way into the flow reactors. New compounds are formed in situ and detected by real-time analyses.
The structures of four compounds (2-5) discovered in this study were confirmed by single crystal X-ray diffraction, however we also studied the synthesis of two different ligands and their coordination behaviour with Cu(I)- precursors under flow.

Results and discussion

To develop our system we opted to investigate the synthesis of a pyridine-moiety with bidentate and tridentate ligands, followed by a complexation reaction employing a metal precursor in the second step. This model system consists of two different ligands – a bidentate \((L^1 = N-(2\text{-pyridinylmethylene})\text{-benzenemethanamine})\) and a tridentate \((L^2 = 2,6\text{-bis(N-benzyliminomethyl)pyridine})\) ligands – and of three different Cu salts – Cu(CH\(_3\)CN)\(_4\)BF\(_4\) and Cu(CH\(_3\)CN)\(_4\)PF\(_6\) (Scheme 1). The two ligands are prepared in situ by reacting benzylamine with 2-pyridincarboxaldehyde and 2,6-pyridinedicarboxaldehyde to obtain \(L^1\) and \(L^2\) respectively. Both ligands are characterised by strong N-donor properties, which allow us to predict the formation of complex structures according to the metal-cation precursor chosen.

The platform was designed to follow the formation of both ligands and complexes by in-line NMR and MS spectrometers. Therefore the platform consists of six 5 mL syringe pumps, two reactors \((V_{R1} \text{ with volume of 2.1 mL and } V_{R2} \text{ with volume of 0.7 mL})\) and the two in-line analytics. A custom designed LabVIEW\textsuperscript{TM} interface allows for the automation and synchronization of multi-step reactions, data acquisition and simultaneous screening of reaction conditions.\textsuperscript{11} This platform allows us to operate in continuous and under semi-inert atmosphere conditions, which is of great advantage working with Cu salts/complexes. Copper (I) chemistry\textsuperscript{12} in particular, is well known for producing interesting molecular structures and the flow platform reported here permits easy manipulation of these reagents in a way that is more difficult under batch conditions.\textsuperscript{13}

Fig. 2 Schematic of the real-time observation in the flow synthesis of \(L^1\) at different residence times showing a comparison of the normalised \(^1H\)-NMR spectra collected during the in-line bench top NMR study.
The first screening consisted on the flow synthesis of L1 and its complexation with Cu(CH3CN)2BF4 or Cu(CH2CN)2PF6, as illustrated in Scheme 1. The synthesis of L1 was obtained in 10 minutes, by mixing into VAl2 2-pyridinedicarboxaldehyde with benzylamine (both as 0.4 M solutions in acetonitrile (MeCN)), having a molar aldehyde : amine ratio of 1 : 1. The formation of L1 was screened in real-time by integrating the flow set-up described with a bench top NMR spectrometer, allowing us to analyse reaction mixtures in non-deuterated solvents. This synthesis was investigated using different flow rates and residence times (see Figure 2), showing a lower conversion to the imine with increasing flow-rate and decreasing of reaction time. The disappearance of the signal corresponding to the aldehyde moiety at 10.00 ppm, and the appearance of the imine proton (as a broad band signal overlapping an aromatic proton signal) at 8.79-8.39 ppm, in addition to the low field shift from 3.77 ppm to 4.82 ppm of the signal relating to the benzylic protons are evidences for the formation of the expected imine (L1).

The synthesis of L1 was further confirmed by substituting the flow NMR with a flow ESI-MS which indicated the presence of the imine as a signal having a m/z = 197.2 (Figure S3 in SI) corresponding to the protonated ligand (L1+H)+.

Complex 1 was synthesised by mixing Cu(CH3CN)2BF4 or Cu(CH2CN)2PF6 (as 0.1 M solutions in MeCN) with L1, having a molar ligand : metal ratio equal to 2 : 1. Also in this case, the formation of 1 was confirmed by in-line 1H-NMR and MS, giving the same results for both metal precursors. Notably, complex 1 was only ever identified using in-line methods whilst under flow conditions and was not crystallised as an isolated product. This synthesis was thus repeated at different flow rates to see how this parameter effects the assembly of compound 1. Complexation occurred at all flow rates and we were able to observe the template effect of the metal-precursor for the ligand-synthesis and the complex itself. From the in-line 1H-NMR measurements, the formation of the complex 1 could be observed in the shift of the proton signals corresponding to the imine. The pyridine protons signal shifts from 8.76-8.39 and 8.18-7.19 ppm to 7.09-8.17 ppm; for the imine proton, new signals appeared at 8.78-8.52 ppm and shifted to 8.21-6.92 ppm and the benzylic protons shifted from 4.82 to 4.77-4.57 ppm, which is higher field compared to the imine (Figure S2 in SI). Similarly, complex 1 could also be detected by in-line MS (m/z = 455.4) (Figure S3 in SI).

As such, this work has allowed us to probe the formation of a transient monomer complex (1), which serves as a common ‘building block’ precursor in the formation of two new multinuclear complexes. Crystallisation of the reaction mixtures containing 1 led to two different compounds according to the Cu precursor used, which result from the assembly of this monomeric sub-unit into different multinuclear complexes. Thus, the brownish-red solution corresponding to 1 obtained using Cu(CH3CN)2BF4 crystallised to yield the dimeric structure 2 after 14 days at 77°C whilst employing Cu(CH2CN)2PF6 gives the trimeric product 3 after 4 days at 18°C (see Figure 3). Here, both complexes are found to contain Cu(II) as indicated by their green-blue colour (opposed to the red-brown colour of the non-oxidised reaction mixture) and their characterisation by X-ray diffraction, which clearly indicates that the tetrahedral Cu(I) centre in the precursor (1) has oxidised in air to Cu(II). Notably, the in-line analyses, in particular NMR, only showed the formation of the sub-unit complex (1) under flow conditions. The sub-unit 1 thus assembles into dimeric (2) and a trimeric (3) structures through inclusion of a bridging carbonate moiety.9 Not only is the spectroscopic (IR for complex 2 and Raman for complex 3), magnetic and analytical data consistent with the assignment of carbonate (see SI), control experiments show that these structures can be easily reproduced by adding dry ice to the crystallisation solution.

![Fig. 3 Molecular structures of dimer complex 2 and trimer complex 3.](Image)

It should be noted that adoption of the flow-platform reported here confers a significant advantage in both the ease with which 2 and 3 can be synthesised from the transient monomer 1 (i.e. no requirement for inert atmosphere) and the reproducibility of this approach, in which the major synthetic variables are closely controlled by automation. The ‘batch’ crystallisation process could be easily reproduced in terms of both yield and purity, as indicated by PXRD (Figure 4).

The second screening consisted on the flow synthesis of L2 and its complexation with Cu(CH3CN)2BF4 (Scheme 1). The formation of L2 was obtained in 4.5 minutes using both reactors (total reactor volume of 2.8 ml as the results of VAl1 + VAl2). For the formation of this tridentate ligand, 2-pyridinedicarboxaldehyde was substituted with 2,6-pyrindenedicarboxaldehyde (as 0.5 M solutions in MeCN) and subsequently reacted with benzylamine, having a molar aldehyde : amine ratio of 2 : 1. This reaction step was monitored both by in-line NMR spectroscopy and ESI-MS and confirmed the formation of the imine. In the 1H-NMR two new signals appeared at 8.50 and 4.86 ppm and two signals corresponding to the starting materials disappeared at 10.08 and 3.78 ppm which is indicative of imine formation (Figure S11a in SI). Similarly, in-line MS observed the formation of L2 corresponding to the appearance of a signal with m/z = 314.4 (L2+H)+ (Figure S12a in SI).
The complexation of \([\text{L}^2]\) with \(\text{Cu(CH}_2\text{CN})_2\text{BF}_4\) (as 0.1 M solutions in MeCN) was obtained using a molar ligand : salt ratio equal to 2 : 1. As in the case of compound \(\text{1}\), this complexation yields a deep red-brown colour, indicative of the formation of Cu(I) complexes. The complete synthesis could be monitored by in-line NMR and ESI-MS. The disappearance of the peak at 10.08 ppm corresponds to the aldehyde protons of 2,6-pyridinedicarboxaldehyde (see Figure 5). Figure 5 A-D shows full conversion into the di-imino ligand by the appearance of the imine at 8.49 ppm and a shift of the bands corresponding to the aromatic ring of the pyridine (from 7.98 and 7.34 ppm to 8.30-7.86 and 7.40-6.88 ppm) and the \(\text{CH}_2\) band from the benzylamine (from 4.86 to 4.57 ppm) confirm the formation of \(\text{L}^2\).

The addition of \(\text{Cu(CH}_2\text{CN})_2\text{BF}_4\) had a significant effect in shifting the bands corresponding to the imine signal, the aromatic rings (from 8.49, 7.98 and 7.34 ppm to 8.30-7.86 and 7.40-6.88 ppm) and the \(\text{CH}_2\) bands (from 4.86 ppm to 4.57 ppm), which is clearly indicative of a change in the environment of the ligand due to complexation (confirmed by controls, see SI). Also, the in-line MS of the reaction solution showed three different signals; two with \(m/z = 689.4\) and 344.8, and a main peak having \(m/z = 376.2\) corresponding to the Cu(I) and Cu(II) analogue of compound \(\text{5}\) directly to compound \(\text{4}\), respectively. Following this, from the reddish brown solution two species could be crystallised, which were subsequently analysed crystallographically (Figure 6). The two copper complexes identified as \([\text{Cu(L}^2\text{j})]^{+}\) (5) and also \([\text{Cu}_2(L^1)_2]^2^+\) (4) via the flow-MS measurements crystallise after several days upon which \(\text{5}\) oxidises to the analogous copper(II) complex (Figure 6, right) whereas \(\text{4}\), remarkably, remains in the same oxidation state as detected in solution (Figure 6, middle).

**Fig. 4** PXRD: top left: simulated pattern from single crystal \([\text{Cu(L}^1\text{j})_2\text{(µ-CO}_2\text{)})_2\text{BF}_4\) (2), top right, simulated pattern from single crystal \([\text{Cu(L}^1\text{j})_2\text{(µ-CO}_2\text{)})_2\text{PF}_6\text{)(OH)}_2\) (3), bottom left: PXRD measurement of reproduced material \(\text{2}\), bottom right, PXRD measurement of reproduced material \(\text{3}\).

**Conclusions**

In summary a new strategy for setting up non-equilibrium reaction conditions for both the synthesis of ligands, and their complexation, was showed in a computer controlled flow system. The use of in-line \(^1\text{H}-\text{NMR}\) and ESI-MS analysis enables the direct observation of reactions in real time and allowed us to discover three new coordination complexes. It is important to note that no additional steps are taken to perform these reactions under anaerobic conditions and so the flow reactor can be considered to provide an
easily controllable pseudo-inert atmosphere for the manipulation of air sensitive reagents. We believe that platforms such as this will be increasingly important in the emerging field of systems chemistry, not to mention the digitalisation of chemistry for chemical discovery, synthesis, and reliable repetition. The platform allows the reaction steps to be handled in an automated way and it is possible to follow the reaction as it proceeds, permitting the discovery of compounds prior to their isolation. The significant advantage of this modular flow set-up is therefore the ability to control self-assembly processes in situ by altering the reaction parameters in real-time (e.g. flow rate, temperatures, and reagents) and observe new compounds in line which are critical to isolate in solid state.

Notes and references
An approach to transfer one pot reactions to a continuous non-equilibrium set-up that allows for real-time observation of the self-assembly of new coordination compounds is presented. Control of the reaction conditions via in-line analytics allows the reaction progress to be followed continuously, permitting the discovery of new compounds in a flow platform.
