ABSTRACT
Peer Instruction (PI) is a student-centric pedagogy in which students move from the role of passive listeners to active participants in the classroom. Over the past five years, there have been a number of research articles regarding the value of PI in computer science. The present work adds to this body of knowledge by examining outcomes from seven introductory programming instructors: three novices to PI and four with a range of PI experience. Through common measurements of student perceptions, we provide evidence that introductory computing instructors can successfully implement PI in their classrooms. We find encouraging minimum (74%) and average (92%) levels of success as measured through student valuation of PI for their learning. This work also documents and hypothesizes reasons for comparatively poor survey results in one course, highlighting the importance of the choice of grading policy (participation vs. correctness) for new PI adopters.

1. INTRODUCTION

Peer Instruction (PI) has gained considerable traction among computer science educators and there have been a number of studies demonstrating its efficacy in a variety of dimensions. Students value PI [5, 8, 10] and learn more in PI classes compared to traditional lecture classes [11, 13]. PI is also associated with low failure rates [6] and increased retention of majors [9].

The vast majority of PI studies in CS take the form of evaluating a single instructor [5, 8, 10] or implementation at a single institution [11, 13]. PI is also associated with low failure rates [6] and increased retention of majors [9].

Our key findings are:

• Consistent with previous studies, a supermajority of students in all studied classes liked and would recommend PI.

• Successful PI implementation requires that the instructor’s motivations for using PI are clear to students.

• The grading policy attached to in-class PI question responses appears to have an effect on student engagement and satisfaction.

2. RELATED WORK

PI is characterized by asking challenging, in-class conceptual questions of students. For each question, students individually respond, discuss the question in small groups, and respond again based on their new understanding [1]. These questions should target common misconceptions and/or core course concepts. To be most effective, PI requires other supporting course changes. For example, many instructors require additional preparation from students before class in order to make best use of limited class time. This preparation can consist of pre-lecture reading and associated quizzes [1, 14] or clicker quizzes at the start of class [14].

Interactive classrooms, including PI classrooms, have shown significant increases in student learning in physics [4].
CS, a number of studies have reported on the success of PI, including improved student satisfaction [5, 8, 10], student learning [7, 15], final exam grades [11, 13], failure rates [6], and retention of majors [9].

The present work provides additional evidence that, for both new and seasoned adopters of PI, students widely laud the change to the course structure. As noted in earlier research [10], it is not always the case that PI is adopted following all recommended practices. The results of the present work lead us to examine ways in which PI is adopted, and we find suggestive evidence that student satisfaction can be significantly impacted by grading clicker results on correctness rather than participation.

3. METHOD

Each of the seven instructors in this study reported the teaching of one introductory programming course. Four of the instructors had experience with PI, either by having taught a course in PI or by having participated significantly in the development of a PI course. The other three instructors were new to PI. We label our courses with two letters: N (novice) or E (experienced) to indicate the instructor’s PI experience, and a letter A-G to differentiate each course (assigned, within N and E categories, by decreasing years of teaching experience for the instructor). Course and instructor characteristics are provided in Table 1.

A brief description of each course is provided below.

Course N-A: CS 1.5 - Object-Oriented Design and Programming: This course concentrates on the object-oriented paradigm, particularly encapsulation, inheritance, and polymorphism. Programming assignments emphasize graphics and event-driven interaction.

Table 1: Institution, course, and instructor characteristics. For major, (decl.) and (ant.) denote declared and anticipated, respectively. N/A denotes data not available.

a Instructor of course E-D had not taught a class using PI, but had been part of PI research and course development. As such, that instructor is considered experienced in PI.

30 minutes each week was spent on a practice code-writing quiz.

Course N-B: CS1 – Computer Science I: This course is an introduction to programming and computer science whose topics include: simple and structured data types, program control structures, problem analysis, algorithm design, and implementation using a high-level language (Java).

Course N-C CS1 – Introduction to Computing I: This Java course covers types/variables, assignment, conditions, loops, classes/objects, files, and arrays.

Course E-D: CS1: This course is an introduction to procedural programming in Python for CS majors covering basic types, expressions, state, control structures, function definition and use, and lists.

Course E-E CS0 – Fluency in Information Technology: This non-majors computing course is required for all psychology majors and as a general education requirement for a subset of university students (those within a specific “college”). The goals of this “general education” course in computing include computational thinking and communicating and collaborating about computational artifacts (in this case Alice programs and Excel sheets).

Course E-F: CS1 – Introduction to Programming in Matlab: This course is an introduction to MATLAB programming for the Cognitive Science department and uses the Media Computation approach [3]. Students study foundational programming constructs such as data manipulation, conditional statements, for-loops, while-loops, and various types of vector and matrix indexing.

Course E-G: CS1 – Computer Science I: This course is a required course for CS and Mathematics majors taught using Media Computation [3]. Concepts include variables, objects, methods, loops, conditionals, and class design.
Table 2: Student feedback on the value of PI. Percentages reflect student agreement. Agreement values under 80% are highlighted.

One instructor, experienced in teaching PI, is known by all instructors and actively assisted the novice instructors in weekly half-hour Skype meetings during their first PI term. The instructors surveyed their students using a common instrument, which enabled comparison of responses across courses.

4. RESULTS

In student self-report surveys, we asked for views on the value of the PI approach in supporting various aspects of the learning experience and views on the instructor’s implementation of PI in the classroom.

4.1 Student Perception of the Value of PI

Students reported on their perception of the value of PI (see Table 2). For all but one question (denoted with a *), higher percentages are better. Responses below 80% positive are highlighted. We note two trends in Table 2.

The first trend is that students overwhelmingly value PI. They report that they pay better attention in class, believe it helps them identify weaknesses earlier, and believe the process helps them learn. As a result, the vast majority of students (91% per class on average) recommend that more instructors use PI in their courses. In two classes, 100% of students would recommend that other instructors use PI. These results demonstrate that across a wide range of institutions and instructors, students both value PI and desire that PI be used by more instructors.

The second trend is that the students in Course N-A perceive PI considerably differently than students in other courses. Compared to students in other courses, the students in Course N-A recommend PI less often, felt discussion was less valuable, and generally reported less value from the PI process. Perhaps most striking is the large percentage (37%) of students who believe the value of a clicker question is only in having the correct answer. We will revisit this anomalous result in the Discussion.

4.2 Student Perception of PI Implementation

Table 3 indicates student satisfaction with how PI was implemented regarding difficulty and timing. To express dissatisfaction, students could respond either “too long”/“too difficult” or “too short”/“too easy.”

The majority of classes saw high degrees of satisfaction with the PI implementation. Both Courses N-A and E-F stand out as having lower levels of satisfaction with the implementation, but recall that only Course N-A experienced the overall lower value of PI.

**Question Difficulty.** In Course N-A, some students (23%) felt that questions were too difficult. Only two other courses had more than 4% of students who reported that questions were too difficult: Course E-F with 14% and Course E-G with 13%.

**Question Time Allowed.** In general, if students were unsatisfied with the time allowed for the initial vote, then they felt that they had too little time (notably in Courses N-A, N-C, E-D, E-E, and E-G) rather than too much time. Course N-A was an outlier with 21% of students responding that they had too little time relative to 7% who felt they had too much time. Although instructors set the questions (and drive the pace), it is critical for students to be given time to think through the questions on their own. Question design (e.g. word choice, clarity, answer options) can seriously impact student time needed to read the question.

**Discussion Time Allowed.** An interesting trend appears regarding time allowed for peer discussion. Of those students who were not satisfied with the time allowed for peer discussion in the courses of all four experienced instructors, more students felt that too much time was allowed. A possible reason for this is that experienced PI instructors are more comfortable spending time on peer discussion, and may have personal evidence suggesting the value of providing students with more time to talk among themselves. For novice instructors, time circulating in the classroom or silently standing up-front can be initially unnerving, and at the very least is a change in their teaching style. However, results in Course N-A more closely match those of courses taught by experienced instructors in that unsatisfied students felt that too much time was allowed. As can be observed from Figure 1, this may be related to the comparatively fewer students in Course N-A who report always discussing with their peers: if some students are not discussing, then they are waiting for class to move forward.
Table 3: Student feedback on the implementation of PI. Percentages reflect students responding “OK” or “About right”. Values under 80% are highlighted.

</tr>
</tbody>
</table>

Class-wide Discussion Time Allowed. Regarding class-wide discussions, unsatisfied students felt that they had too much time in Courses N-A, E-D, E-E, and E-F. Course E-F had the most students reporting that too much time was spent on class-wide discussion (26% too much compared with 11% too little). This instructor had little experience with the programming language used in the course; it is possible that this caused a mismatch between where students struggled and where the instructor anticipated struggles.

Student Behavior during Discussion. Figure 1 provides the breakdown of student responses regarding their discussion habits. For all but one course, the majority of students reported valuing the discussion with their group as it helped them learn. For all courses, only a small minority of students either did not discuss because they did not value discussion or because they were too shy.

Explanation of the Purpose of PI. Figure 2 provides the breakdown of student responses regarding the explanation from the instructor on why clickers were being used. For all but Instructor N-A, more than 90% of students thought that the instructor explained the use of clickers well or did so too much. Instructor N-A had a considerably larger percentage of students reporting that they were unclear why they were using clickers. The other anomalous course result was Course E-G, where 20% of students felt that the instructor explained the use of clickers too much.

5. DISCUSSION

5.1 Value to Students and Instructors

Our results suggest that PI can be successfully adopted at a variety of institutions in introductory computing courses. At least 71% of students (avg. 91%) would recommend that other instructors use this approach in their courses.

The seven instructors in this work all reported a dramatic change in their usual classroom experience upon implementing PI. These instructors varied in terms of reasons for adoption, amount and type of adoption support, and teaching experience. Instructors had varying comfort levels with the courses and varying support for developing and implementing clicker questions. In fact, some had no more to go on than a notion of allowing students to “test” their knowledge. Some read publications on its use, some reviewed clicker slides prepared and used in computing courses, and some had the opportunity to TA for or repeatedly observe an experienced PI instructor. Independent of these background factors, all instructors report that the next time they teach this class, they will teach it with PI.

This said, one course (N-A) stands out as yielding poor survey results compared to the other courses. We next reflect on why this may be the case.

5.2 Exploring Course N-A Differences

Differences between N-A and the other courses can be seen fairly uniformly in both the valuation and implementation
surveys. Through reflective discussion and our reading of PI reports in other disciplines, we highlight two structural issues for discussion. First, the instructor required correctness for a portion of the PI grade (each question was worth 2 points: 1 for correctness and 1 for participation). Second, a notable 25% of the class felt that the instructor did not sufficiently explain why clickers were being used. Together, we posit that these two issues contributed to a very different classroom culture regarding PI, as evidenced by the markedly different student survey responses. In sum, students in Course N-A (more than at those at other institutions):
1. Felt that clicker questions were too hard
2. Felt that too little time was allotted to read and understand questions
3. Did not always discuss with their peers
4. Did not find value in hearing other students provide explanations in class-wide discussion and, 5. Reported lesser perception of the value of PI for their learning.

5.2.1 Grading on Correctness

We suspect that the change from grading on participation to grading on correctness fundamentally changes the atmosphere of the course. Consider the first four points in the above list. This kind of student affect — feelings that questions are too hard and that discussion is not useful — make sense if students perceive PI questions as “standard quiz” questions rather than peer discussion questions. The fact that Instructor N-A gave points for correctness, even though he/she also gave points for participation, may have factored into students perceiving questions as a test of something they should already know, rather than tools designed to build their understanding.

There are two other concerns related to grading on correctness rather than participation. The first is that students become concerned about arguing their interpretation of the question, and this can disrupt the learning process. A focus on learning is hampered when an incorrect answer in the learning process itself has grade-based implications. The second, related issue, is that questions cannot be too difficult or will be viewed as unfair. This is problematic when the recommended correctness range for the individual vote on PI questions is 35-70% [1] and when there is evidence that students benefit considerably more from difficult questions [15]. Instructors who both grade on correctness and recognize the vital part of lecture. With clicker questions, as a student, I approach the “half correct” policy, the instructor was able to reiterate that clicker questions are for helping students engage in developing expert analysis and argumentation skills. The policy reinforced Instructor E-E’s primary course learning goal: getting students to learn how computing people see problems.

A student from Course E-E discusses this policy, noting his/her need to prepare, but expressing satisfaction with the awarding of discussion points:

I have another clicker course, this one is far better. In the other course, every clicker question is graded. It feels too much like the professor just wants to play game show host and puts to [sic] much weight on the correct answers and not the process of getting the answer. This is opposite for this course. I feel like participation should just be graded.

-Student in Course E-G

Given this criticism of grading on correctness, it is essential to examine Course E-E. Like Course N-A, Course E-E had a correctness requirement, but it was differently implemented in a manner that reinforced the role of clicker questions in the learning process rather than the assessment process. In Course E-E, students were graded on participation, but they had to get at least 50% of all questions (including individual and group responses) in each lecture period correct to get those participation points. This approach was devised based on experience in an earlier offering of the course, which required only participation and where students were noted answering randomly and engaging in unrelated activities in the classroom. The instructor believed that a change in policy was needed based on the fact that the course was a required, non-majors course. Students generally did not start the course with a great deal of enthusiasm, nor much understanding of what value the course held for them. In explaining the “half correct” policy, the instructor was able to reiterate that clicker questions are for helping students engage in developing expert analysis and argumentation skills. The policy reinforced Instructor E-E’s primary course learning goal: getting students to learn how computing people see problems.

A student from Course E-E discusses this policy, noting his/her need to prepare, but expressing satisfaction with the awarding of discussion points:

This class was very different from my other classes as it truly made me be on top of my game. I did like the grading structure and how participation points were fair.

-Student in Course E-E

And some students did appear to get the message that their engagement in reasoning about the question, not simply getting points, was the goal.

If in [this course], discussion and proof of understanding is a vital part of lecture. With clicker questions, as a student, I was able to engage in thoughtful reasoning.

-Student in Course E-E

5.2.2 Explaining Pedagogical Change

It is critically important to explain (repeatedly) to students any deviation from expected classroom norms. Students have both experience with and expectations of college classroom learning. They know what happens in a lecture and have techniques that they expect to use in order to learn and measure their progress toward success. From our collective experience, we can report that students claim that they “have to sit at the front of the class” in order to learn/stay awake, want the instructor to “just explain it,” or complain that the lack of lecture “forced me to learn it all myself.” PI completely pulls the rug out from under the students by challenging them to re-examine their established, comfortable, and often perceived successful learning habits.

In a popular 2-page “Tips for Successful Clicker Use” summary, Douglas Duncan (Univ. of Colorado, Astronomy) lists as his second tip: “You MUST MUST MUST explain to students why you are using clickers. If you don’t, they often
assume your goal is to track them like Big Brother, and force them to come to class. Students highly resent this.” (emphasis original)[12]. Perhaps more tellingly, the first item on his list of Practices that Lead to Failure is “1. Fail to explain why you are using clickers.” [2]

In Course N-A, 74% of students report that their instructor explained to the class why he/she was using clickers. However, the remaining 26% of students who felt that clickers were not explained adequately (or at all) was the highest percentage among the courses. This emphasizes the importance of explaining the value of PI not just once and in not just one way. Moreover, for Course N-A, it is likely that students were especially sensitive to this issue as most students had previously taken an introductory course where the instructor used clickers to take attendance. The presence of these kinds of non-pedagogical uses of clickers only heightens the need to explain the pedagogical goals of PI.

5.2.3 Other Factors

Note that, in addition to the two structural issues we have highlighted, Course N-A also differs from other courses in other ways. The course is a CS 1.5 course (not a CS1 course), many of the students used clickers in the past, and the proportion of freshmen is lower. There is little precedence for these differences contributing to the outlying survey results for this course, however. The earliest experience reports of PI in CS report on successful adoption in CS1.5 courses [10], and we know of no evidence suggesting that any novelty of clickers wears off after a single course.

6. CONCLUSION

In this multi-institutional study of student satisfaction in Peer Instruction (PI) courses, we find further evidence of PI being highly valued by students. We also find that one course yielded lower student satisfaction than the other courses. We have argued that this lower satisfaction may have stemmed from two adoption decisions: grading on correctness, and not convincingly arguing to students why clickers and PI are being used. We offer two conclusions here. First, new adopters of PI can expect levels of success similar to those reported by others with considerable PI teaching and development experience. Second, it is important to evaluate adoption decisions. A pedagogy so widely-applicable as PI will inevitably engender debate over the particulars of day-to-day implementation and interaction with students. We encourage all PI instructors to reflect on and make explicit the reasons underlying their PI-based decisions so as to maximize the value of PI for students.

7. ACKNOWLEDGEMENTS

Thank you to the reviewers for their helpful suggestions. This work was supported in part by NSF grant 1140731.

8. REFERENCES
