Morphological awareness and visual processing of derivational morphology in high
functioning adults with dyslexia: An avenue to compensation?

Abstract

This study examined the processing of derivational morphology and its association with measures of morphological awareness and literacy outcomes in 30 Dutch speaking high-functioning dyslexics, and 30 controls, matched for age and reading comprehension. A masked priming experiment was conducted where the semantic overlap between morphologically related pairs was manipulated as part of a lexical decision task. Measures of morphological awareness were assessed using a specifically designed sentence completion task. Significant priming effects were found in each group, yet adults with dyslexia were found to benefit more from the morphological structure than the controls. Adults with dyslexia were found to be influenced by both form (morpho-orthographic) and meaning (morpho-semantic) properties of morphemes while controls were mainly influenced by morpho-semantic properties. Results suggest that morphological processing is intact in high-functioning dyslexics and a strength when compared to controls matched for reading comprehension and age. Thus, supporting morphological processing as a potential factor in the reading compensation of adults with dyslexia. However, adults with dyslexia performed significantly worse than controls on morphological awareness measures.

Keywords: dyslexia, morphological awareness, visual processing, compensation, adults, priming

1. Introduction

Morphology is the study of word formation through the combination of morphemes, the smallest linguistic units of meaning, to form more complex words. Since the objective of writing is not to faithfully encode speech as we speak it, but rather to transmit meaning as efficiently as possible, many writing systems have prioritised the transparency of word roots over the regularity of speech sound, resulting in differences in morphological complexity. An example of this can be seen in the written words ‘heal’ – ‘health’, or by how the various pronunciations of English plurals (i.e. dogs /ˈdɒgz/ and cats /kæts/) are represented by a single ‘s’. The preservation of meaning over sound often produces spelling irregularities in some languages, such as English. However, an increase in morphological complexity has been shown to support reading. The increase of morphological complexity allows individuals to utilise the morphemes of a target word as units of processing through which meaning and associated phonological representations may be extracted from the mental lexicon (Landerl & Reitsma, 2005; Levin, Ravid, & Rapaport, 2001). Therefore, in cases where individuals are limited in their ability to effectively create or access quality phoneme-grapheme correspondences, such as individuals with dyslexia, an awareness of a language’s morphological structure may, in part, offer a means of compensation for any observed literacy impairment (Burani, Marcolini, De Luca, & Zoccolotti, 2008; Elbro & Arnbak, 1996; Law, Wouters, & Ghesquière, 2015). To broaden our understanding of how individuals with dyslexia use morphological structure and its potential role as a compensatory factor, this study explored morphological awareness and morphological processing in typical and dyslexic Dutch readers. Indexes of morphological complexity have placed Dutch as falling

between the more complex French language and English (Bane, 2008). Therefore, the inclusion of a Dutch-speaking population provides a unique bridge through which to discuss and compare past findings of French and English studies. This work will not only broaden the current explanatory models of dyslexia but also aid in furthering the characterization of compensatory factors in individuals with dyslexia.

1.1 Morphological awareness and reading

Morphological awareness (MA) is described as an individual's "conscious (or explicit) awareness of the morphemic structure of words and the ability to reflect on and manipulate that structure" (Carlisle & Feldman, 1995, p. 194). Research has shown MA begins developing prior to reading instruction, yet is often seen to be limited to an awareness of inflectional forms in pre-reading children (Carlisle & Fleming, 2003; Berko 1958; Law, Wouters, & Ghesquière, 2016). Through increased print exposure and instruction, a wider range of morphologically complex words are introduced to children; which in turn stimulates and expands the individual's morphological awareness (Nagy and Anderson, 1984).

Morphological awareness is thought to aid in the identification, comprehension, and pronunciation of words through the analyses of the morphological structure of a target word. Recent studies have demonstrated MA as a contributing factor in word recognition, independent of orthographic processing, phonological awareness (PA), rapid automatized naming, and vocabulary (Carlisle, 2000; Deacon & Kirby, 2004; Roman, Kirby, Parrila, Wade-Woolley, & Deacon, 2009), and in reading comprehension, after controlling for word reading, vocabulary, and PA (Carlisle, 2000; Deacon & Kirby, 2004; Nagy, Berninger, & Abbott, 2006; Tong, Deacon, Kirby, Cain, & Parrila, 2011).

1.2 Morphological processing and reading

Morphological processing (MP) refers to the unconscious or implicit use of the morphological structure of a target word during language processing. Although often discussed as being related to MA, research demonstrating a relation between MP and MA in adult readers is lacking.

Morphological processing is thought to contribute to initial word decoding and increased reading speed of morphologically complex words through the decomposition of a target word into its constituent morphemes, thus aiding in lexical access (Elbro 1989). Additionally, this morphological deconstruction provides additional information to the reader beyond form, such as syntactic, semantic and phonological information, that further aids in word reading, reading comprehension and fluency achievement (Elbro 1989, Mahony, Singson, & Mann, 2000; Nagy et al., 2006).

Support for morphology's role in early visual word recognition has been proved through priming studies demonstrating, across various languages, derivational morphological effects beyond the independent effects of semantics and orthography in early visual word recognition, thus supporting a morphological structure within the lexicon's mental organization (Dutch: Diependaele, Sandra, & Grainger, 2009; English: Marslen-Wilson, Bozic, & Randall, 2008; Rastle, Davis, & New, 2004; Italian: Burani et al., 2008; and Spanish: Duñabeitia, Perea, & Carreiras, 2007). Furthermore, recent studies have shown that the magnitude of morphological priming (i.e. reader –read) is greater than the magnitude of pseudoderived priming ((i.e. corner-corn). These differences have been attributed to the added benefit of the processing of morpho-semantic information above that offered by the morpho-orthographic information. Thus, demonstrating

independent morpho-semantic and morpho-orthographic effects during early visual word recognition (Diependaele, Sandra, & Grainger, 2005; Diependaele et al., 2011; Feldman et al., 2009).

1.3 Dyslexia and morphology awareness and processing

Dyslexia is a hereditary neurological condition often characterised by accuracy and/or fluency difficulties in decoding, word reading, and spelling (Vellutino, Fletcher, Snowling, & Scanlon, 2004). Recent etiological views of dyslexia have suggested a cognitive multi-deficit model to explain the behavioural traits of individuals with dyslexia (Pennington, 2006). Pennington (2006) theorised that multiple genetic or environmental factors act probabilistically as risk or protective factors. It is thought that the probability of the development of the expressed behavioural symptoms is increased or decreased through the interaction of these factors. One such risk factor that is considered to be at the core of dyslexia, and found across all languages, is a deficit in the formation of, and/or access to, phonological representations (Snowling, 2000, but see Ramus & Szenkovits, 2008). Although heavily represented in the literature, phonological impairments are not universal within the dyslexic population and, in turn, not all individuals with phonological impairments develop the behavioural traits associated with dyslexia (Snowling, 2008). However, attention has begun to shift from a single cause model of dyslexia to one embodying multiple risk and protective factors, such as morphological awareness and morphological processing.

Although underrepresented in the literature when compared to studies of phonological skills of individuals with dyslexia, research examining morphological awareness across various ages and languages have shown that dyslexics underperform across a variety of measures assessing MA when compared with chronologically age-matched controls (Berthiaume & Daigle, 2014; Casalis, Colé, & Sopo, 2004; Fowler, Liberman, & Feldman, 1995; Martin, Frauenfelder, & Colé, 2014; Shankweiler et al., 1995; Tsismeli & Seymour, 2006). In studies employing a reading age match design, however, dyslexics were shown to perform similarly to, or better than, younger reading skill matched controls (Robertson, Joanisse, Desroches, & Terry, 2013; Tsismeli & Seymour, 2006; Martin, Frauenfelder, & Colé, 2014; Casalis, Colé, & Sopo, 2004), yet Casalis, Colé, and Sopo, (2004) did find that children with dyslexia were found to be poorer in morphological segmentation tasks when compared with reading-age controls.

Taken together these findings indicate that MA deficits are not causal to a dyslexic's reading struggles, thereby suggesting that MA deficits are a consequence of a poor reading experience, or more primary deficits, such as the phonological deficit often observed in individuals with dyslexia (Snowling 2000; Vellutino & Fletcher, 2005).

In contrast, research of MP has produced little evidence or agreement as to whether or not the ability to rapidly process a word's morphological structure is intact in individuals with dyslexia (Elbro & Arnbak, 1996, Quémart & Casalis, 2015 but see Deacon, Kirby & Parrila, 2006; Lazaro et al., 2013). Theoretically, it has been suggested that a hierarchical structure of linguistic units is employed during early visual word processing, in that the processing of smaller linguistic units (i.e., graphemes) are required to process larger-size units such as rhymes (Duncan, Seymour, & Hill, 1997). Such a

situation would ultimately limit the visual processing of morphemes in a dyslexic population, thus limiting MP. In support of this, a study by Deacon, Parrila, and Kirby (2006) reported evidence suggesting a lack of sensitivity to the derivational structure of written words by high functioning dyslexics. Through the use of a standard lexical decision task, Deacon and colleagues reported that response times of the control group varied between the derived and pseudo-derived test conditions with derived forms being more quickly responded to by controls while similar effects were not found within the high-functioning dyslexics.

However, based on the findings of Feldman, O'Connor & Martin (2009) the results of Deacon Parrila, and Kirby (2006) could be interpreted as an indication of differences in how morpho-orthographic and the morpho-semantic information is utilised during visual word processing. Feldman and colleagues (2009) noted that reaction time differences between derivations and pseudo derivations could be seen as a result of the difference in morpho-semantic and morpho-orthographic processing during visual word recognition. Therefore, the results of Deacon and colleagues (2006) could be interpreted, not as a lack of sensitivity to the derivational structure, but as an indication that individuals with dyslexia may utilise morpho-orthographic and morpho-semantic information differently than controls.

Additional support of intact morphological processing skills of individuals with dyslexia was reported by a recent masked priming study of French-speaking children, which reported significant morphological priming effects in children with dyslexia (Quémart and Casalis, 2013). Findings of Quémart and Casalis (2013) demonstrated a sensitivity to morphological structure of individuals with dyslexia and some level of

morphological organisation of the lexicon. Furthermore, children with dyslexia demonstrated greater prime effects for derived vs. pseudo-derived conditions, which was not observed in controls, suggesting an earlier reliance on the morpho-semantic properties of morphemes during early visual word recognition when compared with controls. These results did differ from our interpretation of Deacon, et al.'s (2006) findings that suggested a greater reliance on morpho-orthographic skills of adults with dyslexia and not morpho-semantic skills. These differences may indicate the possible influence of age and reading experience in the development of morphological processing skill and strategy use of individuals with dyslexia.

1.4 Morphological awareness and morphological processing in compensation

It is theorised that when dealing with novel or less automatized words, dyslexics' phonological impairment limits their reliance on the sublexical route that involves decoding prior to lexical access. Thus, individuals with dyslexia are bound to utilize the lexical route, which in a recent reconceptualization of the dual-route model of reading (Grainger & Ziegler, 2011) has been argued to include not only direct lexical access, but also indirect access through the aid of complex graphemes and morphemes (Deacon & Tong, 2016).

Supporting this notion, Elbro and Arnbak (1996) found that when compared with typical reading age-matched controls, Danish speaking dyslexic adolescents' word reading benefitted more from semantically transparent morphological structures than from semantically opaque control-matched words; controls showed no such benefit. Additionally, in an experiment where participants were presented with a text parsed into morphemes rather than into syllables, Elbro and Arnbak noted that individuals with

dyslexia were found to benefit more from the morphological structure when compared to the syllables. This benefit was not observed in the controls. Furthermore, Law et al. (2015) examined cognitive differences in compensated and non-compensated adult dyslexics based on age appropriate word reading achievement and found that of all the cognitive measures assessed, only MA differed between the two groups. In addition, the MA ability of the compensated dyslexics was found not to differ statistically from the same aged reading-matched controls.

More recently, a French language study by Cavalli, Duncan, Elbro, El Ahmadi, & Colé, (2016) involving university students with and without dyslexia demonstrated the presence of intact morphological skills and their dissociation from the development of phonological knowledge. Cavalli et al. (2016) revealed that the level of dissociation between the quality morphological skills of an individual with dyslexia and their poor phonological skills was highly predictive of reading skills of university students with dyslexia, supporting the notion of morphological awareness and processing as a potential avenue toward achieving compensation in reading.

1.5 The present study

This current study set out to address questions regarding the processing of derivational morphology and morphological awareness and their association with literacy outcomes in high-functioning dyslexic university students with a past diagnosis of dyslexia, who have age appropriate reading comprehension skills. Deacon, Parrila and Kirby (2006) noted that although such a population can achieve age appropriate reading comprehension scores (specifically in untimed testing conditions), high functioning

dyslexics still demonstrate serious word level and reading rate difficulties in addition to phonological processing difficulties.

Specifically, this paper will address the following questions:

1. Do high functioning adults with dyslexia activate morphological information in the initial stages of visual word recognition?
2. Do high functioning adults with dyslexia differ from controls in the use of morphological information during visual word recognition?
3. Do high functioning adults with dyslexics differ from control in their morphological awareness?
4. Can MP and MA be said to be related?
5. Do MP and MA contribute to reading outcomes similarly across both reading groups?

Similar to the study of Quémart & Casalis, (2013) these questions will be addressed through the implementation of a visual masked priming paradigm within a lexical decision task that will utilise specifically designed word lists which allow for the separation of morpho-semantic, morpho-orthographic, orthographic and semantic effects. This testing paradigm has been recognised as a powerful tool to investigate rapid and automatic word recognition, in addition to allowing for the examination of a process that is not within explicit control (Forster & Veres, 1998; Quémart & Casalis, 2013; Rastle, Davis, Marslen-Wilson, & Tyler, 2000).

This study will not only provide a replication of Quémart and Casalis (2013), but will expand on this work through the introduction of an adult high functioning dyslexic

population. The examination of morphological skills and its association to literacy outcomes in such a population will allow for greater understanding of how morphology is used and processed by individuals with dyslexia and its population as a compensatory factor. Furthermore, in comparison to past adult dyslexia studies such as Deacon et al., (2006), the method followed by this study will offer greater control of specific orthographic, semantic, morpho-semantic and morpho-orthographic influences during early visual word processing. Ultimately providing greater insight into how specifically morphological information is used and aids in the reading process.

1.5.1 Hypotheses

We hypothesise that if the participants are able to process the morphological structure of words during early visual word recognition, it could be expected that a significant morphological priming effect in one or both of the morphological conditions (derived or pseudo derived) is observable and to differ from orthographic and semantic controls. As reasoned by Deacon, Parrila and Kirby (2006), if MP is to be considered as a path to compensation in reading comprehension, despite phonological difficulties, we would then expect a greater morphological priming effect within the dyslexic sample when compared to controls. If a significant morphological priming effect is observed in the controls, but not in dyslexics, then it would suggest that, similar to phonological processing, morphological processing is an area of weakness.

If morphological facilitation is observed, then further investigation into the nature of the observed morphological priming effect can be made (see Quémart & Casalis, 2013). Two assumptions could be made regarding the nature of a morphological priming effect. First, as suggested by a form-driven hypothesis, a morpheme's meaning is not

directly involved in morphological processing and, therefore, we would expect to observe similar priming effects in both the morphological and pseudo-derivational conditions. If a group of readers were to rely upon the semantic information contained within the morphemes to process derivational morphology, then the meaning driven hypothesis would predict significant priming effects in the morphological condition alone. As semantic priming is often observed in the later stages of visual word recognition, we do not expect to observe a significant priming effect in the semantic control condition (Diependaele et al., 2005; Rastle, 2000; Bonnotte & Casalis, 2010). Based on the past results discussed earlier, it would be expected to observe morphological facilitation in early visual word recognition for both groups. As seen in Quémart & Casalis (2013) and Elbro and Arnbak (1996) we expect individuals with dyslexia to differ from controls in the pattern of morpho-orthographic and morpho-semantic prime effects. Based on the adult study of Deacon et al. (2006) we would expect this difference to be reflected in the greater reliance on morpho-orthographic information of adults with dyslexia.

We expect to find a relation between aspects of morpho-semantic priming effects and performance on morphological tasks used in our study. It could be argued that the MA tasks used here may rely more heavily upon the semantic and syntactic information than upon the orthographic structure of the morphemes. Therefore, it should be expected that observed morpho-semantic priming effects would be more likely to relate to our measure of morphological awareness.

Lastly, for MP and MA to be considered a variable related to literacy comprehension of adults with dyslexia, we expect that MA and MP do relate to reading

outcomes of individuals with dyslexia and based on the findings of Law et al. (2015) we expect that this relationship will be greater within the dyslexic group than in controls.

2. Method

2.1 Participants

A total of 60 university students were recruited for this study, 30 (20 female and 10 male) typical reading control participants and 30 (23 female and 7 male) participants with dyslexia. All participants were native Dutch-speaking university students at least 18 years of age. All participants reported no history of brain damage, language problems, psychiatric symptoms, visual problems or hearing loss. The participants with dyslexia were recruited through the University's Student Services' Special Needs office and possessed an official diagnosis completed by a registered clinical psychologist in secondary school or earlier. High functioning dyslexics were contrasted with a control group which consisted of normal adult readers with no history of reading difficulty and possessed similar levels of untimed reading comprehension as the high functioning dyslexics ($t(58) = -1.601$; $p = .115$) as shown in Table 1. The adoption of such a control group followed the rationale of Deacon, Parrila and Kirby (2006) to ensure an adequate control group, where similarities in reading (in terms of text complexity) and word experience were better matched than what would have been achieved through the use of a younger word reading age-matched control group. The control population was assembled through class announcements and the placement of posters throughout each campus. Groups were found not to differ across age ($t(58) = -1.298$; $p = .199$) and intelligence as ($t(58) = -.938$; $p = .352$) as measured by Raven's Advanced Progressive Matrices. As expected, the normal reading adult group (NR) was found to perform significantly better

than the dyslexic group (DYS) in both word reading, ($t(58) = -10.563; p < .001$), non-word reading ($t(58) = -9.102; p < .001$) and spelling ($t(58) = -6.697; p < .001$) and phonological awareness (measured with a spoonerism task) ($t(58) = -7.560; p < .001$). Additionally, the control group outperformed the dyslexic group on the measure of vocabulary ($t(58) = -5.298; p < .001$).

2.2 Background measures

To assess the background measures all participants completed a testing battery to provide a better understanding of the cognitive and literacy skills of each group. All tests were administered in a single session between the two experimental morphological processing tasks. Table 1 reports descriptive statistics and t and p -values from independent t -tests for each background measure.

Intelligence (IQ). Intelligence was measured by Raven's Advanced Progressive Matrices test (Raven & Court., 1998) which has a reported substantial test-retest reliability ($r = .83$). This measure required the participants to make judgments related to presented problems and to indicate their choice by pointing to the correct answer. The raw score was calculated as the number correctly identified items for a maximum achievable score of 60.

Reading comprehension was assessed through the use of the GL&SCHR subtest, an original standardised Flemish dyslexia test battery for adults where split half reliability was reported as $r = .71$ (De Pessemier & Andries, 2009). This task required the subjects to read a present text silently and then answer questions about a text. For each of the 18 questions, a score of 0, 1 or 2 was awarded based on the correctness of the response as outlined in the GL&SCHR manual.

Word reading was assessed through the use of the EMT or One Minute Test, which has been found to be a reliable measure ($r = .87$), as determined through the utilisation of a parallel test method (Brus & Voeten, 1999). This timed task required students to read aloud as accurately and quickly as possible a list of 116 Dutch words of increasing difficulty, printed in four columns. The participants were given one minute to read as many words as possible. The raw score was calculated as the number of words read correctly.

Pseudo-word reading. Pseudo-word reading was assessed with the Dutch test, De Klepel (reported reliability of $r = .91$ was determined through the use of a parallel test method) (Van den Bos, Spelberg, Scheepma, & De Vries, 1994). Students were instructed to read aloud as quickly and as accurately as possible a list containing 116 pseudo-words following the Dutch grapheme–phoneme correspondence rules. The raw score was calculated as the number of pseudo-words read correctly to a maximum of 116 in 2 minutes.

Word spelling was assessed through a subtest from the GL&SCHR (De Pessemier & Andries, 2009) which has been found to be a reliable measure for a university level population (Cronbach alpha $r = .76$). Thirty Dutch exception words were read out loud at a rate of one word per 2 seconds. Students were required to write down as many of the words as they could. If needed, the subject was allowed to skip a word and to continue to the next one. Once completed, missed words were repeated without time limits. A point per correctly spelt word was awarded to a maximum of 30.

Phonological awareness. A spoonerism task, taken from the GL&SCHR (De Pessemier & Andries, 2009), was used to assess the subject's phonological awareness. Test re-test

reliability was determined at $r = .90$. For this task two words at a time were presented orally. The subject was required to exchange the first letters of the given words (e.g. Harry Potter will become Parry Hotter). In addition, a reversal task was performed. Participants were to judge if two spoken words were reversals or not, e.g. rac-car. Both time and accuracy were taken into account. A point per correct response was awarded to a maximum of 20.

Vocabulary was assessed by a subtest of the GL&SCHR (De Pessemier & Andries, 2009). Reliability was determined for a university level population through a Cronbach alpha: $r = .90$. Participants were asked to orally give definitions of low-frequency words in the Dutch language; such as the Dutch equivalents of *anonymous* or *simultaneous*. A point per correctly defined word was awarded to a maximum of 25.

Morphological awareness was assessed through an adapted version of the morphological awareness task created Wilson-Fowler (2011). Wilson-Fowler revealed a unidimensional factor structure of morphological awareness and generated a validated, exogenous measure of MA in university students based on two assessment approaches: a derivational suffixes task and non-word sentence completion task. For the purposes of this study, this task was adapted for a Dutch-speaking population.

Derivational suffix task. The derivational suffix task (DST) was based on tasks created by Carlisle (2000). The task required participants to complete 25 visually presented sentence by applying a derivational suffix to a target root word (Dutch example: West. De aanwijzer stuurt ons in westelijke richting. / English equivalent: Act. The secret police arrested the ___ before he could give his speech). The frequency of the stem for each item varied from 0 to 735 words per million ($M1 = 91,21$;

SD1 = 174.64), the frequency of the derived words ranged from 0 to 24 per million (M2 = 5.88; SD2 = 7.14). Of the twenty-five items, 14 were nouns, and 11 were adjectives. The task included items with various combinations of orthographic, semantic or phonological shifts. Instructions, along with four examples, were presented verbally and in writing. The task items are thought to offer a measure of syntactic morphological awareness. Participants could achieve a maximum total score of 25.

Non-word sentence completion task. The non-word sentence completion task (NWSC) was based on Mahony (1994). Participants were instructed to read and complete 27 incomplete sentences. Responses were selected from a list of four possible non-word choices that varied according to the suffix (Dutch example: Fijn dat hij kon rekenen op hun ____ [gruinlijk/gruinig/gruiner/gruinheid]. / An English equivalent: They presented the highly ____ evidence first [credenthive, credenthification, credenthicism, credenthify]). All non-words were composed of a nonsense root or base word combined with a real Dutch suffix. The target words were equally divided between nonsense nouns, adjectives and verb derivatives. Instructions and one example were presented verbally and in writing. Responses were scored as correct or incorrect to a maximum achievable score of 25.

Cronbach's alpha was calculated to assess the internal consistency of the construct of morphological awareness by first submitting all item responses of both MA measures. The analysis resulted in the removal of 10 of the 50 questions. Two questions were removed due to zero variance found, while eight others were removed to strengthen internal consistency. The remaining 40 questions had a high level of internal consistency, as determined by a Cronbach's alpha of 0.75; which exceeds the recommended value of

0.7 or greater (DeVillis, 2003; Kline, 2005). The final composite score of MA was produced through the summation of the remaining 40 questions (20 from each subtest) and standardised.

2.3 Morphological processing

Stimuli and design

The design of the experiment allowed for the manipulation of orthographic, morphological, and semantic links between prime-target pairs across four experimental conditions. The conditions were the following:

(1) morphological (+M+S+O) (e.g. *angstig*–*ANGST*). Prime-targets are morphologically related and morphologically decomposable (+M). The target was orthographically represented within the prime (+O) as well as being semantically related to the prime (+S). An English equivalent would be *jumper* – *JUMP*.

(2) Pseudo-Derivation (+M-S+O) (e.g. *heerlijk* – *HEER*). In this condition, primes are considered as pseudo-derivations, as the primes and targets are not actually morphologically related as they share no semantic overlap (-S), but they can be segmented into an apparent stem and productive derivational affix (+M). Like for instance the English example of *corner*-*CORN*. The pseudo-derivation prime *corner* can be segmented into a stem of *corn* and the derivational affix *-er*, yet the word pair of *corner*-*CORN* are without semantic overlap.

(3) Semantic control (-M+S-O) (e.g. *schip*-*BOOT*) where the target and prime were only semantically related (+S) and the prime was not morphologically decomposable (-M). An English equivalent would be *hound* - *DOG*.

(4) orthographic control (-M-S+O) (e.g. *banket*-*BANK*). In this condition, targets were orthographically related to the primes in that the initial part of the prime contained the target but could not be parsed into existing Dutch morphemes (i.e., *-et* is not a suffix in Dutch). For instance, an English example would be *scandal*-*SCAN*, where the target *scan* can be observed within *scandal* yet the final syllable *dal* of the prime can not be considered a possible derivational affix in Dutch, thus making it not morphologically decomposable.

Each of the four experimental conditions contained 24 prime-target pairs, creating a total of 96 experimental pairs. All targets were free morphemes. Morphological status of the primes was determined using the CELEX Dutch lexical database (Baayen et al. 1995). As in Marslen-Wilson et al. (2008), word pairs were considered morphologically decomposable (+M) when the derived form had a recognisable Dutch suffix which was attached to a potential stem, thus making them morpho-graphically related (or potentially related) as seen in conditions 1 and 2. Semantic relatedness shared between prime-target word pairs, and unrelated filler pairs were evaluated by 25 native Dutch-speaking graduate students from the Linguistics and Educational Sciences departments of the University of Leuven (KU Leuven) in Belgium. Semantic relatedness was rated on a 5-point scale from 1 (definitely not related) to 5 (definitely related). Prime-target pairs for the semantically related condition (+M+S+O and -M+S+O) were selected when word pairs received an average rating of 4 or greater, while pairs for the semantically unrelated condition (+M-S+O and -M-S+O) were chosen when they received an average score of 2 or less.

Targets and primes were matched across the 4 conditions for lemma and word frequency, length, neighborhood size, syllable count, family size and family frequency ($ps > .100$). Primes were matched across all four test conditions for word frequency, lemma frequency and syllable length ($ps > .085$) but could not be perfectly matched for length, $F(3, 110) = 7.020, p < .001$, as the semantic control primes were shorter (mean letters = 5.8) than the morphological (mean letters = 7.2); pseudo-derivation (mean letters = 6.9); orthographic control (mean letters = 6.9) conditions. Additionally primes were unable to be matched perfectly for neighborhood size (N), $F(3, 110) = 7.452, p < .001$. Primes from the semantic control (mean N size = 4.55) condition had more orthographic neighbors than primes in the morphological (mean N size = 1.32), the pseudo-derivation (mean N size = 2.06) and orthographic control (mean N size = 1.51) conditions. Average values for each of these attributes across all conditions are displayed in Table 2.

Similar to the procedure of Marslen-Wilson et al. (2008) each of the 96 targets were associated with an unrelated prime by pseudo-randomizing the primes around the targets. Unrelated control prime target pairs were checked to ensure they shared no morphological, semantic or orthographic relationship. These control prime target pairs provided a baseline allowing for the assessment of priming effects.

To reduce the proportion of related prime-target pairs, an additional set of 24 unrelated prime target pairs were included as fillers in the experiment, generating a total of 192 prime target pairs.

Furthermore, 192 word/non-word pairs were created. Primes consisted of real Dutch words while the non-word targets were orthographically and phonologically

plausible sequences in the Dutch language (e.g. gump, cheme). Similar to Quémart and Casalis (2013), 84 non-word targets were preceded by an orthographically related word while the remaining 108 non-words were preceded by an orthographically unrelated word. Half of the primes of the word/non-word pairs were derived or pseudo-derived words.

Following the procedure of Quémart and Casalis (2013), the 384 items or prime-target pairs were divided into two presentation lists of 192 items, each list containing 96-word targets and 96 non-word targets. All the targets appeared once in each list. In list 1 half of the 96-word targets were associated with a control prime (12-word targets from each of the four conditions) while the other half was associated with an unrelated prime (the remaining 12-word targets from each of the four conditions). Where in list 1 a target word was preceded by an unrelated prime, it was then preceded by a related prime in list 2.

2.3.1 Procedure

Both control and dyslexic subjects were randomly divided into two equal groups where one group was presented list order 1-2 the stimuli were presented to the second group through a list order of 2-1. As each participant completed both experimental lists, an attempt to minimize repetition effect was made by completing the cognitive and literacy tasks described earlier in this paper between the presentations of the two experimental lists. Furthermore, to ensure that the repeated target presentation did not influence priming effects, presentation of the list order (1-2 or 2-1) was entered into the statistical analysis.

Stimuli presentation along with the recording of reaction times and accuracies were controlled for by the PsychoPy version 1.8 software package (Peirce, 2009) running on a Dell Latitude D630 laptop computer. In a random order, each item was displayed in black Times New Roman 42 type on a white background. Each trial began with a 1000 ms fixation cross (+) center on the screen which was then proceeded by a forward mask (#####) displayed for 500 ms. The prime was displayed in lowercase letters for an SOA of 72 ms (Marslen-Wilson et al., 2008; Rastle, 2010). Immediately following, the target word was presented in upper case letters. The target remained on the screen for 5000ms or until the participant responded. Participants were instructed to respond as accurately and as quickly as possible by pressing a designated button on a keyboard to indicate if a letter string was a real word or not. Reaction times were measured from the onset of target presentation until the participant's response. Participants were given 10 practice trials at the beginning of each trail.

To isolate morpho-semantic effect apart from the influence of morpho-orthographic information during the processing of derived forms (as in the morphological condition). Individual priming effects of the pseudo derivational condition were subtracted from the morphological prime condition (+M+S+O) isolating any prime advantage that could be attributed to the processing of morpho-semantic information while controlling for the use of morpho-orthographic information. Thus, resulting in the new variable: morpho-semantic advantage (MS).

3. Results

3.1 Morphological processing

Overall mean rates of correct items for each participant within each experimental condition were calculated. Mean error and mean reaction times (RTs) to correctly responded items in each condition by participant group are presented in Table 3. Data cleaning involved the removal of response times faster than 300 ms or slower than 3000 ms, in addition to outliers that were defined as response times more than 2.5 standard deviations from the mean response time for any given individual in each condition. Priming effects for each condition were calculated as the difference between reaction times of primed and unprimed presentation within each condition (see Table 3). Analysis within each group involved a 4 (condition: Morphological, Pseudo-derivation, Semantic Control, Orthographic Control) X 2 (priming: Related vs. Unrelated) X 2 (order of list presentation: 1 vs. 2) repeated measure ANOVA where reaction times (RTs) acted as the dependent variable. Similar to Deacon et al. (2006) as well as Quémart and Casalis (2013) only significance in the analysis by subjects and not by item was relied upon to reject the null hypothesis. Raaijmakers, Schrijnemakers, and Gremmen (1999) asserted that in experiments employing highly selected and balanced items, as was the case within this study, the null hypotheses may be rejected based solely on a found significance in the analyses by subjects.

3.1.1 Do high functioning adults with dyslexia activate morphological information within the initial stages of visual word recognition?

A main effect of list order was not found, $F(1, 28) = .134, p = .717$, therefore will not be further discussed. Analysis indicated a significant main effect of condition, $F(3,$

84) = 6.728, $p < .001$. A main effect of priming was found to be significant, $F(1, 28) = 6.688, p = .015$, demonstrating faster reaction times for related prime-target pairs than for the unrelated ones. A significant two-way interaction between priming and condition $F(3,84) = 5.285, p = .002$, indicating that the amount of priming differed across the four conditions. Post hoc analysis of the found 2 way interaction revealed that the high functioning dyslexic group showed a significant priming effect in both the morphological, $F(1, 28) = 14.740, p = .001$ (prime effect of 88ms), and pseudo-derivation conditions, $F(1, 28) = 4.697, p = .039$ (prime effect of 49 ms) while not in the orthographic and semantic control conditions [$F(1, 28) = 2.259, p = .144$; $F(1, 28) = 1.462, p = .237$]. Differences between the prime effect of the morphological and pseudo-derivation condition were found to approach significance, $F(1, 28) = 3.765, p = .06$

3.1.2 Do high functioning adults with dyslexia differ from controls in the use of morphological information during visual word recognition?

The control group contrasted with the dyslexics sample as only a significant priming effect in the morphological condition was found $F(1, 28) = 17.999, p < .001$, (prime effect of 31 ms) but not in any of the other three condition, pseudo-derivation: $F(1, 28) = .567, p = .458$; orthographic control: $F(1, 28) = 2.049, p = .163$ and semantic control: $F(1, 28) = .015, p = .903$.

Following the rationale of Deacon et al. (2006) for morphological processing to be considered as a potential compensational path in reading comprehension (as suggested by Elbro & Arnbak, 1996), the morphological priming effects should be expectedly greater for dyslexics than for the controls. An examination across both groups of the

priming effects of both derived (morphological condition) and pseudo-derivation conditions revealed a significant difference where dyslexics were found to benefit more from the morphological structure of the prime in both conditions when compared to controls with similar reading comprehension levels (morphological condition: $t(49.9) = -6.732; p < .001$); pseudo derived condition: $t(49.9) = -6.732; p < .001$).

3.2 Do high functioning adults with dyslexics differ from control in their morphological awareness.

Adults with dyslexia were found to significantly underperform controls on our MA measure, as seen in Table 1. These results were found to support past research of MA of children and adults with dyslexia. As MA is often found to be closely associated with vocabulary and phonological awareness an ANCOVA was run to determine the effect of group differences concerning normal and dyslexic readers on morphological awareness while controlling for vocabulary and phonological awareness. After adjustment for vocabulary knowledge and PA (as measured by the spoonerism task) the initially observed poorer performance of readers with dyslexia was maintained, $F(1, 56) = 12.170, p = .001, \text{partial } \eta^2 = .179$.

3.3 Do performances on MP, and MA tasks share any commonality?

To examine the relationship between performance on MA and MP tasks Pearson correlations were conducted between the morphological priming effect and the composite score of morphological awareness within each group. Results demonstrated that morphological awareness differed between groups in its relationships with measures of MP. MA's relationship with the new variable of morpho-semantic advantage was found to significantly differ between groups ($p = 0.024$), for MA and ms where were only found

to be significantly related within the high-functioning dyslexic participants ($r = .513$; $p = .004$). MA was not related to any other measure of morphological priming effect within the control population or dyslexics ($ps > .060$).

3.4 Does MP and MA contribute to reading outcomes similarly across both reading groups?

To examine the relationship between morphological awareness and morphological processing with the performance on the assessed literacy background measures Pearson correlations were conducted within each group (see Table 4). Different patterns of significant relations of MA and MP and literacy measures were observed across the two groups. Within the control group the composite score of MA was found to be significantly related to spelling ($r = .487$, $p = .006$) in addition to reading comprehension significantly relating to ms ($r = .410$, $p = .025$). Yet, within the dyslexic group spelling was found to be significantly related to both the ms ($r = .548$, $p = .002$) and morpho-orthographic priming effect (as measured through the pseudo-derivation condition) ($r = .461$, $p = .010$), while a trend toward a significant relationship between spelling and MA was observed ($r = .355$, $p = .054$). Additionally, word reading and non-word reading were found to be significantly related to ms ($r = .433$, $p = .017$; and $r = .466$, $p = .009$). Further analysis comparing the differenced of these relations between groups found ms's relation with spelling to significantly differ between dyslexics and controls ($Z = 1.8$, $p = 0.036$), while group differences between the relation of word reading and nonword reading with ms were found to be approaching significance ($Z = 1.48$, $p = 0.069$; $Z = 1.49$, $p = 0.068$).

Due to the found group differences on the measure of vocabulary ($t(58) = -5.298$; $p < .001$) additional analyses at all levels were conducted controlling for this difference. All patterns of significance reported above were maintained when controlled for vocabulary, with the addition of the finding of a significant correlation of spelling and MA within the high-functioning dyslexic group ($r = .368$, $p = 0.049$).

4. Discussion

The current study set out to address questions regarding the processing of morphologically derived forms and its association with measures of morphological awareness and literacy outcomes in high-functioning dyslexics, defined as university students with a past diagnosis of dyslexia with age appropriate reading comprehension skills. Similar to Deacon et al. (2006) the high-functioning dyslexics were compared to a control group of age-matched peers with similar reading comprehension ability.

The background variables of the dyslexic group were found to be consistent with much of the literature, as they were found to perform significantly poorer on measures of phonological processing, spelling, as well as word and non-word reading when compared to a normal reading population (Deacon et al., 2006; Vellutino et al., 2004).

A masked priming experiment was conducted to examine morphological facilitation during early visual word recognition as well as the effects produced by the shared semantic (meaning) and orthographic (form) overlap between morphologically related primes (conditions 1 and 2). Ultimately, we were aiming to determine if high functioning adults with dyslexia implicitly use morphological information within the initial stages of visual word recognition and whether they differed from controls in how

morpho-semantic and morpho-orthographic information influenced this facilitation during visual word recognition.

Results demonstrate significant morphological priming effects for the dyslexic readers in both the morphological and pseudo-derived conditions. These findings differed from the controls who were only found to have a significant morphological priming effect at our prime duration of 72 ms, fitting with the results of Rastle and colleagues (2000). Significant priming effects were not found in the orthographic and semantic control conditions in either group. These patterns of priming suggest that high-functioning dyslexics indeed benefit from morphological facilitation during early visual word recognition and this effect can be distinguished from priming attributed to general orthographic and semantic overlap alone. These results support the hypothesis first put forth by Elbro and Arnbak (1996) and builds on previous research (Burani et al., 2008; Quémart & Casalis, 2013), which suggested that irrespective of their decoding deficits, dyslexics can process morphemic units rapidly and automatically.

As reasoned earlier, for morphological processing to be considered as a potential path to compensation (as suggested by Elbro & Arnbak, 1996), it should be expected that morphological priming effects would be greater for dyslexics than for the controls. A significant difference of priming effect of morphological facilitation between the two groups was observed. Dyslexics were shown to benefit more from the morphological structure of the prime compared to controls with similar reading comprehension levels. These results support the notion that morphological processing is not only intact in high-functioning dyslexics but also a strength compared to age and reading comprehension matched controls. Morphological processing, therefore, may well be an avenue to achieve

compensation within reading comprehension for individuals with dyslexia. Linkin and Zur Hagit (2006) as well as Burani et al. (2008) theorized that due to dyslexic readers' poor decoding abilities and often slow and less automated whole word processing, individuals with dyslexia must rely on morphological decomposition to aid lexical access, as was depicted in the previously discussed re-conceptualized dual route model of reading (Grainger & Ziegler, 2011). Linkin and Zur Hagit (2006) went on to propose that to overcome their poor decoding skills; dyslexic readers develop an increased morphological sensitivity. The results of this study support this theory.

Secondly, our experimental design allows for the determination of whether or not the overlap in form and meaning between morphologically related words is required for high-functioning dyslexic readers to benefit fully from morphological facilitation during visual word recognition. To our knowledge, this is the first study to examine differential effects of morpho-semantic and morpho-orthographic processing in a masked priming paradigm within a population of adults with dyslexia.

Similarly to the study of Feldman et al. (2009), the priming effect found for the morphological condition was observed to be larger than the effect within the pseudo-derivation condition (although was only found to be approaching significance). Diependaele et al. (2009) discussed these differences as a feature of the hybrid model of morphological processing. This model predicts that both morpho-semantic and morpho-orthographic properties are activated in parallel when a reader is presented with a morphologically complex word. The parallel activation, in turn, generates a feedback connection through the interaction of the morpho-semantic and morpho-orthographic routes, resulting in a noticeable increased priming effect. This differs from the slower

pseudo-derivation conditions that were reliant on a single activation at the morpho-orthographic level.

Past research in dyslexic children by Quémart and Casalis (2013), found that at 60 ms of visual prime presentation dyslexic children differed from controls in the use of both morpho-semantic (meaning) and morpho-orthographic (form) properties of morphemes to benefit from morphological facilitation during visual word recognition this early time point. Although at a longer 72 ms prime presentation, the results of this study do support previous findings of differences between dyslexics and controls in the use of morphological information. Our results did differ from the pattern of findings reported by Quémart and Casalis (2013) as dyslexics were found to make use of both morpho-orthographic and morpho-semantic information while the processing of morpho-orthographic information did not offer any measurable advantage for controls.

As our study differed from that of Quémart and Casalis (2013) in two key areas, prime duration and participant age, two possible arguments could be made to explain the differences in these patterns of results. Firstly it could be argued that with the increase of age dyslexic individuals may increase their flexibility to process morpho-orthographic properties alongside morpho-semantic processing. A more likely explanation could be attributed to the natural evolution of various forms of facilitation during early word visual recognition, as those noted by past time-course studies, such as Rastle and colleague (2000). Therefore the observed difference in the influence of morpho-semantic and morpho-orthographic information between our findings and those reported by Quémart and Casalis may be evidence of an alternative time-course of facilitation within individuals with dyslexia when compared with controls. Future time-course studies

utilising a range of SOA will need to be conducted within individuals with dyslexia to help further address these questions.

4.1 Morphological awareness in high-functioning adults with dyslexia

To date, we are unaware of any study to examine the role of MA in Dutch-speaking adults with dyslexia. Our study found that adults with dyslexia performed worse on measures of MA when compared with age-matched controls. Similar results have been found across various languages in adults (Nagy et al., 2006; Law et al., 2015; Leikin and Zur Hagit, 2006) and children (Carlisle & Feldman, 1995; Deacon & Kirby, 2004; Nagy et al., 2006). Our results are in agreement with these past findings, which conclude that individuals with dyslexia have a deficit in MA relative to typical readers of the same age. Yet, previous studies have also demonstrated that individuals with dyslexia perform as well as or better than younger, reading age-matched controls on MA tasks, which suggests that the MA deficit observed in dyslexics is not causal of their word reading deficit and is potentially a consequence of their poor reading experience or poor phonological awareness skills (Cavalli et al., 2016; Martin, Frauenfelder, & Colé, 2014; Tsesmeli & Seymour, 2006; Robertson et al., 2013).

4.2 Relations between MA, MP and literacy

To examine whether the relationships between measures of morphological and literacy achievement were different in the two groups, with dyslexia vs. controls, correlations were calculated separately within each group. Our results found that only morpho-semantic advantage was related to MA within the dyslexic group. That lack of a significant relationship between morpho-orthographic properties and MA may have been a function of the MA test design. The two MA tests employed in the study both relied

less on form and more heavily on the semantic and syntactic information of the target morphemes. For instance in the Non-word sentence completion task students had to judge which of the provided non-words (all containing plausible Dutch affixes) completed the sentence. To execute this task subjects had to rely specifically on the syntactic and semantic information conveyed by the affix only.

MS's pattern of significant relations with literacy measures also differed between groups. Morpho-semantic priming effects were found to be strongly related to spelling, word and non-word reading in the dyslexic group while only relating to reading comprehension in controls. Although morpho-orthographic information were found to facilitate increased morphological decomposition within the dyslexic subjects (as evidenced by the significant prime effect found for the pseudo-derived condition), the results of our correlational analysis support the argument of Elbro and Arnbak's (1996) which states that individuals with dyslexia may rely more on the morpho-semantic properties of morphemes to aid their performance during time sensitive literacy measures (as in the word and non-word reading tasks administered in this study).

Spelling's relationship with morphological awareness and within both groups was expected. Similarly across various languages, Caravolas (2004) points out that spelling is not only based on phoneme-grapheme correspondence but also on morphemes and other orthographic patterns that may not be directly predicted at the phoneme level.

Although considered to be a relatively transparent language, Dutch does contain numerous cases of words that are not spelt using phonological but rather morphological principles (see Rispoli et al., 2004). Therefore, it can be expected that spelling is

facilitated by morphology as morphemes are often considered to be more consistent and transparent with respect to the morphological structure of words (Caravolas, 2004).

4.3 Limitations and future perspectives

The reliance of a single SOA (72 ms) during the priming task could be seen as a limitation of this study. Studies that have examined morphological facilitation over a time-course of varying SOAs demonstrated that the scale of visible morphological priming effects changes as a function of SOA (Marslen-Wilson et al., 2008; Rastle, 2000). Rastle (2000) found that in normal reading adults the priming effect for pseudo-derivation conditions was larger and significant at shorter SOAs of 43ms than compared to an SOA of 72 ms where significance was not found. The examination of prime-target pairs at different SOAs may have yielded a different pattern of results. The general slow speed of information processing associated with individuals with dyslexia (Bowers & Wolf, 1993; Breznitz & Misra, 2003) may have skewed what would have been considered a normal pattern of results at an SOA of 43ms to a longer SOA of 72 ms. Future research would need to conduct a time course study of varying SOAs to examine if the observed pattern of results is unique to an SOA of 72 ms or if dyslexics consistently differ over time in how morphological facilitation aids early visual word recognition.

Additionally, the limitation posed by the MA tasks reliance on semantic and syntactic information also may have obscured the observation of potential relationships between morpho-orthographic priming effects and many of the literacy tasks. As this study has demonstrated that differential effects of the various levels of information contained within a morpheme are observable, future studies should take care in the selection and design of MA measures. Although Law et al., 2015 did demonstrate intact

morphological awareness skills of compensated adults with dyslexia through the use of the same MA testing design, it should be noted that the visual presentation of the MA tasks represents a limit of the study since the dyslexic group had reading difficulties. Future MA task design should focus on oral presentation and the balanced use of the syntactic, semantic, orthographic and phonological properties and information of morphemes within the tasks.

Lastly, to better understand morphology's role as an avenue to compensation, future studies should attempt to examine not only compensated or high-functioning dyslexics, but also non-compensated dyslexics.

5. Acknowledgements

We would like to acknowledge the help and support of Christine Swennen, Dr. Ditte Kimps and Dr. Natalia Pericchi Pagá in the design and balancing of the measures. This research has been financed by the research fund of the KU Leuven (grants dBOF/12/014 and OT/12/044).

Tables 1-4 for: Morphological awareness and visual processing of derivational morphology in high functioning adults with dyslexia: An avenue to compensation?

Table 1: Participant characteristics and performance on background literacy and phonological processing measures

Measures	NR		DYS		<i>t</i>	p
	M	SD	M	SD		
Non-verbal IQ	26.30	5.15	27.59	5.70	-0.938	.352
Word Reading	102.03	11.25	70.93	11.37	-10.563	<.001*
Spelling	25.47	2.69	19.53	4.04	-6.697	<.001*
Reading comprehension	22.07	4.48	20.27	4.23	-1.800	.115
Pseudo word reading	102.79	12.61	68.30	16.21	-9.102	<.001*
Vocabulary	13.03	3.34	8.77	2.89	-5.298	<.001*
Spoonerism	64.50	31.30	17.37	13.65	-7.560	<.001*
Morphological awareness (z-score)	0.00	1.00	-2.25	1.53	-6.732	<.001*

Notes. * significance maintained after adjusting for multiple comparisons.

Table 2. Mean values for item attributes across testing condition

Condition	Lemma frequency		Word frequency		Length		<i>N</i> size		Syllable count		Family size	Family frequency
	Prime	Target	Prime	Target	Prime	Target	Prime	Target	Prime	Target	Target	Target
Morphological (M+S+O+)	16.8	111.7	12.4	30.7	7.2	4.3	1.3	9.9	2.2	1.1	52.4	6481.1
Pseudoderivation (+M-S+O)	55.1	104.1	44.14	97.0	6.9	4.2	2.1	11.3	2.1	1.1	70.5	7757.6
Sematic control (-M+S-O)	79.7	121.7	57.7	68.0	5.8	4.2	4.6	9.7	1.6	1.1	79.4	4545.3
Orthographic control (-M-S+O)	25.4	103.3	10.1	49.5	6.9	4.0	1.5	13.0	2.2	1.0	52.24	9041.2

Note: *N* size corresponds to the mean number of orthographic neighbors (neighborhood size)

1 Table 3. Mean (standard deviation) RTs (ms) and error percentages for control and dyslexic
 2 groups according to the condition and priming relationship.

	Control		DYS	
	RT	Error%	RT	Error %
Morphological (M+S+O+)				
Related	619 (78)	2.1 (3.2)	772 (107)	3.5 (3.9)
Unrelated	650 (72)	1.5(2.3)	860 (179)	3.7 (3.7)
Priming effect (ms)	31 ^{**}		88 ^{**}	
Pseudo-derivation (M+S-O+)				
Related	643(77)	1.8 (3.6)	791 (130)	2.8 (2.8)
Unrelated	650(69)	2.3 (2.6)	840 (146)	3.2 (3.7)
Priming effect (ms)	7		49 [*]	
Semantic Control (M-S+O-)				
Related	623 (63)	0.3 (1.1)	769 (124)	1.1 (1.9)
Unrelated	636 (62)	4.2 (1.6)	796 (137)	1.5 (2.5)
Priming effect (ms)	13		27	
Orthographic Control (M-S-O+)				
Related	651 (76)	1.0 (2.8)	809 (136)	1.3 (2.3)
Unrelated	649 (71)	0.8 (2.0)	834 (158)	1.8 (3.0)
Priming effect (ms)	2		25	

Note: RTs, reaction times; +/-M, Morphologically decomposable/not decomposable; +/-S, Semantically highly related/unrelated; +/-O: Orthographic overlap high/low. * $p < .05$, ** $p < .001$

3
 4
 5 Table 4: Pearson correlations between measures of literacy and morphological knowledge within
 6 each group . Upper right -control participants; lower left - Dyslexic

Measure	1	2	3	4	5	6	7
1. MA	--	.028	.085	.487 ^{**}	.131	.077	.100
2.MS	.513 ^{**}	--	.458 [*]	.126	.062	.098	.410 [*]
3. MO	.225	.366 [*]	--	.139	.232	.003	.121
4. Spelling	.355 [^]	.548 ^{**}	.461 [*]	--	.319	.382 [*]	.275
5. Word_Read	.037	.433 [*]	.161	.178	--	.526 ^{**}	.161
6. NonWord	.130	.466 ^{**}	.057	.502 ^{**}	.666 ^{***}	--	.129
7. Read_Comp	.309	.134	.071	.356	.186	.285	--

Note. MA: Morphological awareness; ms: morpho-semantic advantage; MO: morpho-orthographic; Word_Read: word reading from the one minute word reading test; NonWord: non word reading task; Read_Comp: reading comprehension

[^] $p < .06$. * $p < .05$. ** $p < .01$. *** $p < .001$.
