Modelling and Solving the Stable Marriage Problem
Using Constraint Programming

Abstract
We study the Stable Marriage problem (SM), which is a combinatorial problem that arises in many practical applications. We present two new models of an instance $I$ of SM with $n$ men and $n$ women as an instance $J$ of a Constraint Satisfaction Problem. We prove that establishing arc consistency in $J$ yields the same structure as given by the established Extended Gale/Shapley algorithm for SM as applied to $I$. Consequently, a solution (stable matching) of $I$ can be derived without search. Furthermore we show that, in both encodings, all stable matchings in $I$ may be enumerated in a failure-free manner. Our first encoding is of $O(n^3)$ complexity and is very natural, whilst our second model, of $O(n^2)$ complexity (which is optimal), is a development of the Boolean encoding in [Gent et al., 2001], establishing a greater level of structure.

1 Introduction
The classical Stable Marriage problem (SM) has been the focus of much attention in the literature over the last few decades [Gale and Shapley, 1962; Knuth, 1976; Gusfield and Irving, 1989; Roth and Sotomayor, 1990]. An instance of SM comprises $n$ men, $m_1, \ldots, m_n$, and $n$ women, $w_1, \ldots, w_n$, and each person has a preference list in which they rank all members of the opposite sex in strict order. A matching $M$ is a bijection between the men and women. We denote the partner in $M$ of a person $q$ by $M(q)$. A (man,woman) pair $(m_i, w_j)$ blocks a matching $M$, or forms a blocking pair of $M$, if $m_i$ prefers $w_j$ to $M(m_i)$ and $w_j$ prefers $m_i$ to $M(w_j)$. A matching that admits no blocking pair is said to be stable, otherwise the matching is unstable. SM and its variants arise in important practical applications, such as the annual match of graduating medical students to their first hospital appointments in a number of countries (see e.g. [Roth, 1984]).

Gale and Shapley [Gale and Shapley, 1962] showed that every instance $I$ of SM admits a stable matching, and gave an $O(n^2)$ algorithm, linear in the instance size, for finding such a matching in $I$. A modified version of this algorithm – the Extended Gale/Shapley (EGS) algorithm [Gusfield and Irving, 1989, Section 1.2.4] – avoids some unnecessary steps by deleting from the preference lists certain (man,woman) pairs that cannot belong to a stable matching. Moreover the EGS algorithm aids the development of some useful structural properties of SM [Gusfield and Irving, 1989, Section 1.2.4]. The man-oriented version of the EGS algorithm (henceforth referred to as the MEGS algorithm) involves a sequence of proposals from the men to the women, provisional engagements between men and women, and deletions from the preference lists. A pseudocode description of MEGS algorithm is given in Figure 1 (the term delete the pair $(p, w)$ means that $p$ should be deleted from $w$’s list and vice versa.) The stable matching returned by the MEGS algorithm is called the man-optimal (or equivalently, woman-pessimal) stable matching, denoted by $M_0$, since each man has the best partner (according to his ranking) that he could obtain, whilst each woman has the worst partner that she could obtain, in any stable matching. A similar proposal sequence from the women to the men yields the woman-oriented EGS (WEGS) algorithm. This gives rise to the woman-optimal (or man-pessimal) stable matching, denoted by $M_0$, with analogous properties. Upon termination of the MEGS algorithm, the reduced preference lists that arise following the deletions are referred to as the MGS-lists. Similarly, the WGS-lists arise upon termination of the WEGS algorithm. The intersection of the MGS-lists with the WGS-lists yields the GS-lists [Gusfield and Irving, 1989, p.16]. Some important structural properties of the GS-lists are given by the following theorem.

Theorem 1 ([Gusfield and Irving, 1989, Theorem 1.2.5]). For a given instance of SM:

(i) all stable matchings are contained in the GS-lists;

(ii) no matching $M$ contained in the GS-lists can be blocked by a pair that is not in the GS-lists;

(iii) in the man-optimal (respectively woman-optimal) stable matching, each man is partnered by the first (respectively last) woman on his GS-list, and each woman by the last (respectively first) man on hers.

assign each person to be free;

while some man \( m \) is free and \( m \) has a nonempty list loop

\( w = \) first woman on \( m \)'s list; \( \{ m \text{'proposes'} to \ w \} \)

if some man \( p \) is engaged to \( w \) then

assign \( p \) to be free;

end if;

assign \( m \) and \( w \) to be engaged to each other;

end loop;

Figure 1: The man-oriented Extended Gale/Shapley algorithm for SM and SMI.

An example SM instance \( I \) is given in Figure 2. (We assume that a person’s preference list is ordered with his/her most-preferred partner leftmost.) This figure also indicates those preference list entries that belong to the GS-lists. In \( I \), the man-optimal stable matching \( M_0 \) and the woman-optimal stable matching \( M_2 \) are as follows:

\[
M_0 = \{(m_1, w_1), (m_2, w_3), (m_3, w_2), (m_4, w_4)\}
\]

\[
M_2 = \{(m_1, w_3), (m_3, w_2), (m_4, w_4), (m_4, w_3)\}
\]

The extension SMI of SM arises when preference lists may be incomplete. This occurs when a person may find a member of the opposite sex unacceptable. If a person \( p \) finds a person \( q \) unacceptable, \( q \) does not appear on the preference list of \( p \). In the SMI case, a matching \( M \) in an instance \( I \) of SM is a one-one correspondence between a subset of the men and a subset of the women, such that \( (m, w) \in M \) implies that each of \( m \) and \( w \) finds the other acceptable. Given a matching \( M \) in an SMI instance, a pair \( (m, w) \) blocks a matching \( M \) if each of \( m \) and \( w \) finds the other acceptable, and each is either unmatched in \( M \) or prefers the other to their partner in \( M \). If a person \( p \) finds a person \( q \) unacceptable, then \( p \) and \( q \) cannot be paired in any stable matching, nor can they form a blocking pair. Hence, from the point of view of finding stable matchings, we lose no generality by assuming that \( q \) finds \( p \) unacceptable also, so that preference lists are consistent. It is straightforward to adapt the EGS algorithm to the SMI case [Gusfield and Irving, 1989, Section 1.4.2] – see Figure 1 for a pseudocode description. The woman-oriented algorithm is analogous. In the SMI context a stable matching need not be complete; however the same set of men and women are matched in all stable matchings [Gale and Sotomayor, 1985]. Furthermore, the concept of GS-lists can be extended to SMI, with analogous properties (for Property (ii) in Theorem 1, each person with a non-empty GS-list should be matched in \( M \); for Property (iii), each person with an empty GS-list is unmatched in both stable matchings).

1.1 Related work

The Stable Marriage problem has its roots as a combinatorial problem, but has also been the subject of much interest from the Game Theory and Economics community [Roth and Sotomayor, 1990] and the Operations Research community [Vate, 1989]. In recent years SM and SMI have also been the focus of interest from the Constraint Programming community [Aldershof and Carducci, 1999; Dye, 2001; Gent et al., 2001; Lustig and Puget, 2001; Gent and Prosser, 2002a; 2002b; Green and Cohen, 2003; Thorn, 2003]. These papers have presented a range of encodings of SM and its variants as an instance of a Constraint Satisfaction Problem (CSP). In all references apart from [Gent et al., 2001], structural relationships between the effect of Arc Consistency (AC) propagation [Bessière and Régin, 1997] and the GS-lists were not explored in detail, nor did the authors consider the aspect of failure-free enumeration.

However such issues were considered by Gent et al. [Gent et al., 2001], who proposed two CSP encodings of SMI. For each model, it was shown that AC propagation can be used to achieve similar results to the EGS algorithm in a certain sense. The first encoding creates a CSP instance \( J_1 \) using a set of ‘conflict matrices’ to encode an SMI instance \( I \). In \( J_1 \), AC may be established in \( O(n^3) \) time, following which the variables’ domains correspond to the GS-lists of \( I \). The second encoding creates a Boolean CSP instance \( J_2 \). In \( J_2 \), AC may be established in \( O(n^2) \) time, however the variables’ domains after AC propagation only correspond to a weaker structure called the XGS-lists in \( I \), which in general are supersets of the GS-lists in \( I \). (The XGS-list for a person \( p \) consists of all entries in \( p \)’s preference list between the first and last entries of his/her GS-list inclusive.) In both encodings the set of all stable matchings in \( I \) can be enumerated in a failure-free manner (using a value-ordering heuristic in the case of the first encoding).

1.2 Our contribution

The work of [Gent et al., 2001] left open the question as to whether there exists an \( O(n^2) \) CSP encoding of SM that captures exactly the structure of the GS-lists. In this paper we present two encodings of an instance \( I \) of SMI (and so of SM) as a CSP instance \( J \). Again, for each encoding, we show that AC propagation achieves the same results as the EGS algorithm in a precise sense. The first model is a natural \( (n+1) \)-valued encoding of SMI; it bears some resemblance to the encoding of SM given in [Lustig and Puget, 2001] and develops the ‘conflict matrices’ model of [Gent et al., 2001]. In this model we show that AC propagation may be carried out in \( O(n^3) \) time. Our model is more intuitive, and is more time and space-efficient, than the ‘conflict matrices’ model. Our second model is a more compact \( 4 \)-valued encoding that develops the Boolean encoding from [Gent et al., 2001] – in this case we show that AC propagation may be carried out in \( O(n^2) \) time. For both models we prove that the GS-lists in \( I \) correspond to the domains remaining after establishing AC in \( J \). Furthermore, we show that, for both encodings, we are guaranteed a failure-free enumeration of all stable matchings.
in \( I \) using AC propagation combined with a value-ordering heuristic in \( J \). Our second encoding therefore answers the question left open by [Gent et al., 2001].

Our results show that, provided the model is chosen carefully, AC propagation within a CSP formulation of SMI captures the structure produced by the EGS algorithm. Moreover our second encoding indicates that AC propagation can be achieved within the same time complexity as the (optimal) MEGS algorithm for SMI, producing equivalent structural results. This strengthens the assertion in [Gent et al., 2001] regarding the applicability of constraint programming to the general domain of stable matching problems. Furthermore, in many practical situations there may be additional constraints that cannot be accommodated by a straightforward modification of the EGS algorithm. Such constraints could however be built on top of either of the two models that we present here. Possible extensions could arise from variants of SMI that are NP-hard [Ronn, 1990; Ng and Hirschberg, 1991; Kato, 1993; Manlove et al., 2002].

We remark that, independently, Unsworth and Prosser have formulated a specialised \( n \)-ary constraint for SMI, such that AC propagation gives rise to the GS-lists, where the complexity of establishing AC is \( O(n^2) \) [Unsworth and Prosser, 2005a]. They have also constructed a specialised binary constraint for SMI that yields the same structure, where AC may be established in \( O(n^3) \) time [Unsworth and Prosser, 2005b]. In both cases, all stable matchings may be generated using a failure-free enumeration.

The remainder of this paper is organised as follows. Section 2 contains the \((n+1)\)-valued encoding. We show that AC may be established in \( O(n^3) \) time, proving the structural relationship between AC propagation and the GS-lists. This is followed by the failure-free enumeration result for this model. In Section 3 we present the \( 4 \)-valued encoding, following a similar approach, however in this case we show that AC may be established in \( O(n^2) \) time. Finally, Section 4 contains some concluding remarks.

2 \((n + 1)\)-valued encoding

2.1 Overview of the encoding

In this section we present an \((n + 1)\)-valued binary CSP encoding for an instance \( I \) of SMI. We assume that \( M = \{m_1, m_2, \ldots, m_n\} \) is the set of men and \( W = \{w_1, w_2, \ldots, w_n\} \) is the set of women in \( I \) (it is not difficult to extend our encoding to the case that the numbers of men and women are not equal, but for simplicity we assume that they are equal). For each man \( m_i \in M \) and woman \( w_j \in W \), the length of \( m_i \)'s and \( w_j \)'s preference list is denoted by \( l^w_i \) and \( l^m_j \) respectively. We let \( L \) denote the total length of the preference lists in \( I \). Also, for any person \( z \in M \cup W \), we let \( PL(z) \) denote the set of persons on \( z \)'s original preference list in \( I \), and we let \( GS(z) \) denote the set of persons on \( z \)'s GS-list in \( I \). For each man \( m_i \in M \) and woman \( w_j \in PL(m_i) \), we denote the position of \( w_j \) on \( m_i \)'s original preference list (regardless of any deletions that may be carried out by the MEGS/WEGS algorithms) by \( rank(m_i, w_j) \), with \( rank(w_j, m_i) \) being similarly defined. If \( w_j \in W \setminus PL(m_i) \), then \( rank(m_i, w_j) \) and \( rank(w_j, m_i) \) are undefined.

We define a CSP encoding \( J \) for an instance \( I \) of SMI by introducing \( 2n \) variables to represent the men and women in the original instance \( I \). For each man \( m_i \in M \), we introduce a variable \( x_i \) in \( J \) whose domain, denoted by \( dom(x_i) \), is initially defined as \( dom(x_i) = \{1, 2, \ldots, l^m_i\} \cup \{n + 1\} \). Similarly, for each woman \( w_j \in W \), we introduce a variable \( y_j \) in \( J \) whose domain, denoted by \( dom(y_j) \), is initially defined as \( dom(y_j) = \{1, 2, \ldots, l^w_j\} \cup \{n + 1\} \).

An intuitive meaning of the variables is now given. Informally, if \( x_i = p \ (1 \leq p \leq l^m_i) \), then \( m_i \) marries the woman \( w_j \) such that \( rank(m_i, w_j) = p \), and similarly for the case that \( y_j = q \ (1 \leq q \leq l^w_j) \). More formally, if \( \min dom(x_i) \geq p \ (1 \leq p \leq l^m_i) \), then the pair \((m_i, w_j)\) has been deleted as part of the MEGS algorithm applied to \( I \), for all \( w_j \) such that \( rank(m_i, w_j) < p \). Hence if \( w_j \) is the woman such that \( rank(m_i, w_j) = p \), then either \( m_i \) proposes to \( w_j \) during the execution of the MEGS algorithm or the pair \((m_i, w_j)\) will be deleted before the proposal occurs. Similarly if \( \min dom(y_j) \geq q \ (1 \leq q \leq l^w_j) \), then the pair \((m_i, w_j)\) has been deleted as part of the WEGS algorithm applied to \( I \), for all \( m_i \) such that \( rank(m_i, w_j) < q \). Hence if \( m_i \) is the man such that \( rank(w_j, m_i) = q \), then either \( w_j \) proposes to \( m_i \) during the execution of the WEGS algorithm or the pair \((m_i, w_j)\) will be deleted before the proposal occurs. If \( x_i = n + 1 \) (respectively \( y_j = n + 1 \)) then \( m_i \) (respectively \( w_j \)) is unmatched upon termination of each of the MEGS or WEGS algorithms applied to \( I \).

The constraints used for the \((n + 1)\)-valued encoding are shown in Figure 3. In the context of Constraints 1 and 4, \( j \) is the integer such that \( rank(m_i, w_j) = p \); also \( q = rank(w_j, m_i) \). In the context of Constraints 2 and 3, \( i \) is the integer such that \( rank(w_j, m_i) = q \); also \( p = rank(m_i, w_j) \).

An interpretation of Constraints 1 and 3 is now given (a similar interpretation can be attached to Constraints 2 and 4 with the roles of the men and women reversed). First consider Constraint 1, a stability constraint. This ensures that if a man \( m_i \) obtains a partner no better than his \( p^{th} \)-choice woman \( w_j \), then \( w_j \) obtains a partner no worse than her \( q^{th} \)-choice man \( m_i \). Now consider Constraint 3, a consistency constraint. This ensures that if man \( m_i \) is removed from \( w_j \)'s list, then \( w_j \) is removed from \( m_i \)'s list.

2.2 Arc consistency in the \((n + 1)\)-valued encoding

We now show that, given the above CSP encoding \( J \) of an SMI instance \( I \), the domains of the variables in \( J \) following AC propagation correspond to the GS-lists of \( I \). That is, we prove that, after AC is established, for any \( i, j \) \((1 \leq i, j \leq n)\), \( w_j \in GS(m_i) \) if and only if \( p \in dom(x_i) \), and similarly \( m_i \in GS(w_j) \) if and only if \( q \in dom(y_j) \), where \( rank(m_i, w_j) = p \) and \( rank(w_j, m_i) = q \).

Figure 3: The constraints for the \((n + 1)\)-valued encoding of an instance SMI.
The proof is presented using two lemmas. The first lemma shows that the arc consistent domains are equivalent to subsets of the GS-lists. This is done by proving that the deletions made by the MEGS and WEGS algorithms applied to \( I \) are correspondingly made during AC propagation. The second lemma shows that the GS-lists correspond to a subset of the domains remaining after AC propagation. This is done by proving that the GS-lists for \( I \) give rise to arc consistent domains for the variables in \( J \).

**Lemma 2.** For a given \( i \) (\( 1 \leq i \leq n \)), let \( p \) be an integer (\( 1 \leq p \leq l_i^n \)) such that \( p \) \( \in \) \( \text{dom}(x_i) \) after AC propagation. Then the woman \( w_j \) such that \( \text{rank}(m_i, w_j) = p \) belongs to the GS-list of \( m_i \). A similar correspondence holds for the women.

**Proof.** The GS-lists are constructed as a result of the deletions made by the MEGS and WEGS algorithms applied to \( I \). We show that the corresponding deletions are made to the relevant variables’ domains during AC propagation. In the following proof, only deletions made by the MEGS algorithm are considered; a similar argument can be used to prove the result for an execution of the WEGS algorithm.

We prove the following fact by induction on the number of proposals \( z \) during an execution \( E \) of the MEGS algorithm. If proposal \( z \) consists of man \( m_i \) proposing to woman \( w_j \) with \( \text{rank}(m_i, w_j) = p \) and \( \text{rank}(w_j, m_i) = q \), then \( x_i \geq p \) and \( y_j \leq q \) for each man \( m_i \) such that \( \text{rank}(w_j, m_k) = s \) \( (q < s \leq l_j^n) \), \( x_k \neq r \), where \( \text{rank}(m_k, w_j) = r \).

Consider the base case where \( z = 1 \). Then \( p = 1 \). Since \( x_i \geq 1 \), propagation of Constraint 1 yields \( y_j \leq q \). Then for each \( s \) \( (q < s \leq l_j^n) \), propagation of Constraint 3 gives \( x_k \neq r \) such that \( \text{rank}(m_k, w_j) = s \) and \( \text{rank}(w_j, m_k) = r \).

Now suppose that \( z = c > 1 \) and that the result holds for \( z < c \). We consider the cases where \( p = 1 \) and \( p > 1 \).

**Case (i).** For \( p = 1 \) the proof is similar to that of the base case.

**Case (ii).** Now suppose that \( p > 1 \). Let \( w_l \) be any woman such that \( \text{rank}(m_i, w_l) = r < p \). Then \( w_l \) has been deleted from \( m_i \)'s list during the MEGS algorithm. Now suppose \( \text{rank}(w_l, m_j) = s_1 \). Then \( m_i \) was deleted from \( w_l \)'s preference list because she received a proposal from a man \( m_k \) whom she prefers to \( m_i \), where \( \text{rank}(w_l, m_k) = s_2 < s_1 \). Since \( m_k \) proposed to \( w_l \) before the \( p \)-th proposal, we have by the induction hypothesis that \( y_l \leq s_2 \), so that \( y_l \neq s_1 \) and \( x_l \neq r \). But \( w_l \) was arbitrary and hence \( x_l \neq r \) for \( 1 \leq r \leq p-1 \), so that \( x_i \geq p \). The rest of the proof is similar to that of the base case.

**Lemma 3.** For each \( i \) \( (1 \leq i \leq n) \), define a domain of values \( \text{dom}(x_i) \) for the variable \( x_i \) as follows: if \( \text{GS}(m_i) = \emptyset \), then \( \text{dom}(x_i) = \{n + 1\} \); otherwise \( \text{dom}(x_i) = \{\text{rank}(m_i, w_j) : w_j \in \text{GS}(m_i)\} \). The domain of each \( y_j \) \( (1 \leq j \leq n) \) is defined analogously. Then the domains so defined are arc consistent in \( J \).

**Proof.** To show that the variables’ domains are arc consistent we consider each constraint in turn.

First consider Constraint 1 and suppose that \( x_i \geq p \). Then during the execution of the MEGS algorithm applied to \( I \), either (i) \( m_i \) proposed to \( w_j \), or (ii) the pair \( (m_i, w_j) \) was deleted, where \( \text{rank}(m_i, w_j) = p \) and \( \text{rank}(w_j, m_i) = q \). We consider the two cases below:

**Case (i)** If \( m_i \) proposed to \( w_j \) during the execution of the MEGS algorithm, then all men ranked below \( m_i \) on \( w_j \)'s list are deleted, i.e. \( y_j \leq q \) as required.

**Case (ii)** If \( (m_i, w_j) \) was deleted during the execution of the MEGS algorithm then \( w_j \) must have received a proposal from a man \( m_k \) whom she prefers to \( m_i \), where \( \text{rank}(w_j, m_k) = s \) \( (s < q) \). Therefore the MEGS algorithm deletes all those men \( m_z \) from \( w_j \)'s list such that \( \text{rank}(w_j, m_z) > s \), i.e. \( y_j \leq s < q \) as required.

Next consider Constraint 3. Suppose that \( y_j \neq q \), so that during an execution of either the MEGS or WEGS algorithms, \( m_i \) is deleted from \( w_j \)'s list, where \( \text{rank}(w_j, m_i) = q \). To ensure that the preference lists are consistent, the same algorithm deletes \( w_j \) from \( m_i \)'s list, i.e. \( x_i \neq p \), where \( \text{rank}(m_i, w_j) = p \), as required.

Verifying Constraints 2 and 4 is similar to the above with the roles of the men and women reversed and the MEGS algorithm exchanged for the WEGS algorithm.

The two lemmas above, together with the fact that AC algorithms find the unique maximal set of arc consistent domains, lead to the following theorem.

**Theorem 4.** Let \( I \) be an instance of SMI, and let \( J \) be a CSP instance obtained by the \((n+1)\)-valued encoding. Then the domains remaining after AC propagation in \( J \) correspond to the GS-lists of \( I \) in the following sense: for any \( i, j \) \( (1 \leq i, j \leq n) \), \( w_j \in \text{GS}(m_i) \) if and only if \( p \in \text{dom}(x_i) \), and similarly \( m_i \in \text{GS}(w_j) \) if and only if \( q \in \text{dom}(y_j) \), where \( \text{rank}(m_i, w_j) = p \) and \( \text{rank}(w_j, m_i) = q \).

The constraints shown in Figure 3 may be revised in \( O(1) \) time during propagation, assuming that upper and lower bounds for the variables’ domains are maintained. Hence the time complexity for establishing AC is \( O(ed) \), where \( e \) is the number of constraints and \( d \) is the domain size [van Hentenryck et al., 1992]. For this encoding we have \( e = O(n^2) \) and \( d = O(n) \), therefore AC may be established in \( O(n^3) \) time; also the space complexity is \( O(L) \). These complexities represent an improvement on the ‘conflict matrices’ encoding in [Gent et al., 2001], whose time and space complexities are \( O(n^8) \) and \( O(L^2) \) respectively. Moreover we claim that the model that we present in this section is a very natural and intuitive encoding for SMI.

Theorems 4 and 1(iii) show that we can find a solution to the CSP giving the man-optimal stable matching \( M_0 \) without search: for each man \( m_i \in M \), let \( p = \text{min} \text{dom}(x_i) \). If \( p = n + 1 \) then \( m_i \) is unmatched in \( M_0 \), otherwise the partner of \( m_i \) is the woman \( w_j \in W \) such that \( \text{rank}(m_i, w_j) = p \). Considering the \( y_j \) variables in a similar fashion gives the woman-optimal stable matching \( M_0 \).

In fact we may go further and show that the CSP encoding yields all stable matchings in \( I \) without having to backtrack due to failure. That is, we may enumerate all solutions of \( I \) in a failure-free manner using AC propagation in \( J \) combined with a value-ordering heuristic. The following theorem, proved in [Manlove and O’Malley, 2005], describes the enumeration procedure.
Let \( I \) be an instance of SMI and let \( J \) be a CSP instance obtained using the \((n+1)\)-valued encoding. Then the following search process enumerates all solutions in \( I \) without repetition and without ever failing due to an inconsistency:

- AC is established as a preprocessing step, and after each branching decision, including the decision to remove a value from a domain;
- if all domains are arc consistent and some variable \( x \) has two or more values \( y \) in its domain, then the search proceeds by setting \( x \) to the minimum value \( p \) in its domain. On backtracking, the value \( p \) is removed from the domain of \( x \);
- when a solution is found, it is reported and backtracking is forced.

### 3 4-valued encoding

#### 3.1 Overview of the encoding

In this section we present a CSP encoding of SMI that is more complex but more efficient than the \((n+1)\)-valued encoding given in Section 2.1. We assume the notation as defined for an instance of SMI in the first paragraph of Section 2.1.

We construct a CSP encoding \( J \) for an SMI instance \( I \) by introducing \( L \) variables, each of which represents a preference list. For each man \( m_i \) (\( 1 \leq i \leq n \)) we introduce \( l_i^m \) variables \( x_{i,p} \) \((1 \leq p \leq l_i^m)\), corresponding to the members of \( PL(m_i) \). Similarly for each woman \( w_j \) \((1 \leq j \leq n)\) we introduce \( l_j^m \) variables \( y_{j,q} \) \((1 \leq q \leq l_j^m)\). As before the domain of a variable \( z \) is denoted by \( dom(z) \); initially each variable is given the domain \( \{0,1,2,3\} \).

An intuitive meaning of the variables’ values is given in Figure 4. The table indicates that deletions carried out by the MEGS and WEGS algorithms applied to \( J \) are reflected by the removal of elements from the relevant variables’ domains. In particular, removal of the value 2 (respectively 3) from a variable’s domain corresponds to a preference list entry being deleted by the MEGS (respectively WEGS) algorithm applied to \( J \). Note that potentially a given preference list entry could be deleted by both algorithms. Also, if the value 0 is removed from \( dom(x_{i,p}) \) \((1 \leq i \leq n, 1 \leq p \leq l_i^m)\), then either \( m_i \) is removed from \( PL(m_i) \) during the MEGS algorithm (where \( rank(m_i, w_j) = p \)) or the entry is deleted prior to the proposal occurring. Similarly if the value 0 is removed from \( dom(y_{j,q}) \) \((1 \leq j \leq n, 1 \leq q \leq l_j^m)\), then either \( w_j \) proposes to \( m_i \) during the WEGS algorithm (where \( rank(w_j, m_i) = q \)) or the entry is deleted prior to the proposal occurring.

The constraints for this encoding are listed in Figure 5. In the context of Constraints \( 4 \) and \( 10 \), \( j \) is the integer such that \( rank(m_i, w_j) = p \); also \( q = rank(w_j, m_i) \). In the context of Constraints \( 5 \) and \( 9 \), \( i \) is the integer such that \( rank(w_j, m_i) = q \); also \( p = rank(m_i, w_j) \). Further, we remark that Constraints \( 4 \) and \( 9 \) are present only if \( q + 1 \leq l_j^m \) and \( p + 1 \leq l_i^m \) respectively.

An interpretation of each constraint is now given. Firstly consider Constraint 1. This constraint is used to start the proposal sequence and can be interpreted as each man initially proposing to the first woman on his list during the MEGS algorithm. Constraint 2 states that if \((m_i, w_j)\) has been deleted by the MEGS algorithm for all \( w_j \) such that \( rank(m_i, w_j) < p \), and \((m_i, w_j)\) has also been deleted, where \( rank(m_i, w_j) = p \), then \((m_i, w_j)\) has been deleted by the MEGS algorithm for all \( w_j \) such that \( rank(m_i, w_j) \leq p \). Hence, if \( p + 1 \leq l_i^m \), \( m_i \) will subsequently propose to the woman \( w_j \) such that \( rank(m_i, w_j) = p + 1 \) during the MEGS algorithm, or the pair \((m_i, w_j)\) will be deleted before the proposal occurs. Constraint 3 states that if a woman’s \( q^{th} \)-choice partner is deleted during an iteration of the MEGS algorithm, then her \((q+1)^{th} \)-choice partner should also be deleted. Constraint 4 shows a stability constraint: this ensures that if man \( m_i \) obtains a partner no better than \( w_j \), then \( w_j \) obtains a partner no worse than \( m_i \). Lastly Constraint 5 is a consistency constraint: this ensures that if \( m_i \) is removed from \( w_j \)’s list during the MEGS algorithm then \( w_j \) is also removed from \( m_i \)’s list. Constraints 6-10 have a similar meaning with the roles of the men and women reversed, and with MEGS replaced by WEGS.

#### 3.2 Arc consistency in the 4-valued encoding

We now prove that, given the above CSP encoding \( J \) of an SMI instance \( I \), the domains of the variables in \( J \) following AC propagation correspond to the GS-lists of \( I \). That is, we prove that, after AC is established, for any \( i, j \) \((1 \leq i, j \leq n)\), \( w_j \in GS(m_i) \) if and only if \( \{2, 3\} \subseteq dom(x_{i,p}) \), and similarly \( m_i \in GS(w_j) \) if and only if \( \{2, 3\} \subseteq dom(y_{j,q}) \), where \( rank(m_i, w_j) = p \) and \( rank(w_j, m_i) = q \).

In order to prove this correspondence, we define the GS-domains for the variables in \( J \) as follows. Initially let each variable in \( J \) have domain \( \{0,1,2,3\} \). Run the MEGS algorithm on instance \( I \). Then use rules (ii), (i), and (v) in Figure 4 to remove 0’s and 2’s from the appropriate domains, obtaining CSP instance \( J' \) from \( J \). Next run the WEGS algorithm on the original instance \( I \). Now use rules (iii), (iv), and (vi) in Figure 4 to remove 0’s and 3’s from the appropriate domains in \( J' \), obtaining CSP instance \( J'' \). The domains of the variables in \( J'' \) are referred to as the GS-domains.

As in Section 2.2, two lemmas are used to prove that enforcing AC gives the GS-lists. The first lemma shows that the domains remaining after AC propagation are equivalent to subsets of the GS-lists. This is done by proving that if a deletion is made as part of either the MEGS or WEGS algorithms, then a corresponding deletion is made during AC propagation. The second lemma shows that the GS-lists correspond to a subset of the domains remaining after AC is enforced. This is done by proving that the GS-domains for \( J \) are arc consistent.

**Lemma 6.** For a given \( i \) \((1 \leq i \leq n)\), let \( p \) be an integer such that \( \{2, 3\} \subseteq dom(x_{i,p}) \) after AC propagation. Then the woman \( w_j \) such that \( rank(m_i, w_j) = p \) belongs to the GS-list of \( m_i \). A similar correspondence holds for the women.

**Proof.** The GS-lists are obtained through deletions made by the MEGS and WEGS algorithms. We prove that the corresponding deletions are made to the relevant variables’ domains during AC propagation. In particular, suppose that...
In this proof, only deletions made by the MEGS algorithm are considered; a similar argument can be used for deletions made by the WEGS algorithm. It suffices to prove the following by induction on the number of proposals $z$ during an execution $E$ of the MEGS algorithm. If proposal $z$ consists of man $m_i$ proposing to woman $w_j$, with $\text{rank}(m_i, w_j) = p$ and $\text{rank}(w_j, m_i) = q$, then $x_{i,p} > 0$, $y_{j,s} \neq 2$ ($q < s \leq l_j^p$), and for each man $m_k$ such that $\text{rank}(w_j, m_k) = s$, $0 \leq q < s \leq \frac{l_j^p}{p}$, $x_{k,r} \neq 2$, where $\text{rank}(m_k, w_j) = r$.

First consider the base case where $z = 1$. Then $p = 1$. By Constraint 1, $x_{i,1} > 0$, and by Constraint 4 we have $y_{j,q+1} \neq 2$. Hence by Constraint 3, it follows that $y_{j,s} \neq 2$ for each $s$ ($q < s \leq l_j^p$). Also for each such $s$, propagation of Constraint 5 ensures that $x_{k,r} \neq 2$, where $\text{rank}(w_j, m_k) = s$ and $\text{rank}(m_k, w_j) = r$.

Now suppose that $z = c > 1$ and that the result holds for $z < c$. We consider the cases where $p = 1$ and $p > 1$.

**Case (i)** For $p = 1$ the proof is similar to that of the base case.

**Case (ii)** Now assume that $p > 1$. Let $w_i$ be any woman such that $\text{rank}(m_i, w_i) = r < p$. Then $w_i$ has been deleted from $m_i$'s list during the MEGS algorithm. Now suppose that $\text{rank}(w_i, m_k) = s_1$. Then $m_k$ was deleted from $w_i$'s list because she received a proposal from a man $m_k$ whom she prefers to $m_i$, where $\text{rank}(w_i, m_k) = s_2 < s_1$. Since $m_k$ proposed to $w_i$ before the $s_1$-th proposal, by the induction hypothesis it follows that $x_{i,r} \neq 2$. However since $w_i$ was arbitrary, it follows that $x_{i,r} \neq 2$ for $1 \leq r < p$. From Constraint 2 we have $x_{i,1} > 0$, and hence the propagation of Constraint 2 $(p - 1)$ times yields $x_{i,p} > 0$. The rest of the proof is similar to that of the base case.

**Lemma 7.** The GS-domains (corresponding to the GS-lists in $I$) are arc consistent in $J$.

**Proof.** We consider each constraint in turn to show that the GS-domains are arc consistent.

Clearly Constraint 1 is satisfied, as $p = 1$ in rule (i) of Figure 4, i.e. $x_{i,1} > 0$. Now consider Constraint 4 and suppose that $x_{i,p} > 0$. Then during the execution of the MEGS algorithm, either (i) $m_i$ proposed to $w_j$, or (ii) the pair $(m_i, w_j)$ was deleted, where $\text{rank}(m_i, w_j) = p$ and $r \neq 2$. But if $r \neq 2$, then $x_{i,p} \neq 2$.

</table>
rank\( (w_j, m_i) = q \). Assuming \( q + 1 \leq l_p^w \), we consider the two cases separately.

Case (i) If \( m_i \) proposed to \( w_j \) during the execution of the MEGS algorithm, then \( w_j \) deletes all those men ranked below \( m_i \) on her preference list, so that in particular, \( y_{j,q+1} \neq 2 \).

Case (ii) If the pair \( (m_i, w_j) \) was deleted during the execution of the MEGS algorithm, then \( w_j \) must have received a proposal from a man \( m_k \) whom she prefers to \( m_i \). Consequently, all men ranked below \( m_k \) on \( w_j \)'s list are deleted by the MEGS algorithm, so that in particular, \( y_{j,q+1} \neq 2 \).

Now suppose that \( y_{j,q} \neq 2 \). Then by construction of the GS-domains, the MEGS algorithm deleted the man \( m_i \) such that \( rank(m_i, w_j) = p \). So in addition, 2 is removed from the domain of \( x_{i,p} \), where \( rank(m_i, w_j) = p \), satisfying Constraint 5. Also, as in Case (ii) above, \( y_{j,q+1} \neq 2 \), satisfying Constraint 3.

Now consider Constraint 2 and suppose that \( x_{i,p} \neq 2 \) and \( x_{i,p} > 0 \). Then \( w_j \) has been removed from the list of \( m_i \), where \( rank(m_i, w_j) = p \). Also \( x_{i,p} > 0 \) implies that either (i) \( p = 1 \), or (ii) \( x_{i,r} \neq 2 \) (\( 1 \leq r < p \)). We consider the two cases separately.

Case (i) If \( p = 1 \), we have \( x_{i,1} \neq 2 \), and hence \( x_{i,2} > 0 \) by construction of the GS-domains.

Case (ii) As \( x_{i,p} > 0 \), it follows that \( x_{i,r} \neq 2 \) (\( 1 \leq r < p \)). Also \( x_{i,p} \neq 2 \). Hence \( x_{i,r} \neq 2 \) (\( 1 \leq r \leq p \)), so that \( x_{i,p} > 0 \) by construction of the GS-domains.

A similar argument can be used to verify that Constraints 6-10 are satisfied. Here the roles of the men and women are reversed and MEGS is replaced by WEGS.

The two lemmas above, together with the fact that AC algorithms find the unique maximal set of arc consistent domains, lead to the following theorem.

**Theorem 8.** Let \( I \) be an instance of SMI, and let \( J \) be a CSP instance obtained by the 4-valued encoding. Then the domains remaining after AC propagation in \( J \) correspond to the GS-lists of \( I \) in the following sense: for any \( i, j \) (\( 1 \leq i, j \leq n \), \( w_j \in GS(m_i) \) if and only if \( [2, 3] \subseteq dom(x_{i,p}) \), and similarly \( m_i \in GS(w_j) \) if and only if \( [2, 3] \subseteq dom(y_{j,q}) \), where \( rank(m_i, w_j) = p \) and \( rank(w_j, m_i) = q \).

In general AC may be established in \( O(ed^n) \) time, where \( e \) is the number of constraints, \( d \) the domain size, and \( r \) the arity of each constraint [Bessière and Régin, 1997]. In the context of the 4-valued encoding, it follows that \( e = O(L) \), \( d = O(1) \), and \( r = 2 \), and hence AC may be enforced in time \( O(L) = O(n^2) \). The time complexity of \( O(L) \) is linear in the size of \( I \) and gives an improvement over the encoding presented in Section 2.1. Moreover \( O(L) \) is also the time complexity of the EGS algorithm, which is known to be optimal [Ng and Hirschberg, 1990]. The space complexity of the 4-valued encoding is also \( O(L) \).

Theorems 8 and 1(iii) show that we can find a solution to the CSP giving the man-optimal stable matching \( M_0 \) without search: for each man \( m_i \in M \), if \( [2, 3] \subseteq dom(x_{i,p}) \) for each \( r (1 \leq r \leq l_m^o) \) then \( m_i \) is unmatched in \( M_0 \), otherwise we let \( p \) be the unique integer such that \( dom(x_{i,p}) = \{1, 2, 3\} \) and define the partner of \( m_i \) to be the woman \( w_j \in W \) such that \( rank(m_i, w_j) = p \). Considering the \( y_j \) variables in a similar way gives the woman-optimal stable matching \( M_z \).

As in Section 2, we may go further and show that the CSP encoding yields all stable matchings in \( I \) without having to backtrack due to failure. As before we enumerate all solutions of \( I \) in a failure-free manner using AC propagation in \( J \) combined with a value-ordering heuristic, however in this case, maintenance of AC is much less expensive. The following theorem, proved in [Manlove and O’Malley, 2005], describes the enumeration strategy in this context.

**Theorem 9.** Let \( I \) be an instance of SMI and let \( J \) be a CSP instance obtained from \( I \) using the 4-valued encoding. Then the following search process enumerates all solutions in \( I \) without repetition and without ever failing due to an inconsistency:

- AC is established as a preprocessing step, and after each branching decision, including the decision to remove a value from a domain;
- if all domains are arc consistent and some variable \( x_{i,p} \) has \( \{0, 1, 2, 3\} \) in its domain, then we let \( p \) be the unique integer such that \( dom(x_{i,p}) = \{1, 2, 3\} \) and choose \( p' \) to be the minimum integer (\( p < p' \)) such that \( dom(x_{i,p'}) = \{1, 2, 3\} \);
- the search proceeds by removing the value \( 3 \) from the domain of \( y_{j,q} \). On backtracking, the value 2 is removed from the domain of \( y_{j,q} \) where \( rank(m_i, w_j) = p \) and \( rank(w_j, m_i) = q \);
- when a solution is found, it is reported and backtracking is forced.

### 4 Concluding remarks

In this paper we have described two models for the Stable Marriage problem and its variant SMI as a CSP. Our first encoding is very natural and may be used to derive the GS-lists following AC propagation, although the time complexity for establishing AC is worse than that of the EGS algorithm. Our second encoding, whilst more complex, again yields the GS-lists, but this time the time complexity for AC propagation is optimal. Using both encodings we are able to find all stable matchings for a given instance of SMI using a failure-free enumeration without search.

A natural extension of this work is to the case where there is indifference in the preference lists. It has already been demonstrated [Gent and Prosser, 2002a; 2002b] that the earlier encodings of [Gent et al., 2001] can be extended to the case where preference lists in a given SMI instance may include ties, suggesting that the same should be possible with the models that we present here. Another direction is to consider the Hospitals / Residents problem (HR) (a many-one generalisation of SMI). The \( (n+1) \)-valued encoding from this paper, and the specialised constraints from [Unsworth and Prosser, 2005a; 2005b], have already been generalised to the HR case (see [Manlove et al., 2005] for further details).

Finally, it remains to conduct an empirical investigation of the encodings presented in this paper, based on randomly-generated and real-world data. Such investigations have already been carried out for other encodings for SM and its variants [Gent and Prosser, 2002a; 2002b; Unsworth and Prosser, 2005a; 2005b].
Acknowledgements
We would like to thank Rob Irving and Patrick Prosser for helpful comments on earlier drafts of this paper. We would also like to thank Patrick Prosser for suggesting that previous (man-oriented and woman-oriented) versions of the models that we present here could be amalgamated.
