Introduction

The development of organic light-emitting diodes (OLEDs) has grown rapidly since the first report by Tang and Van Slyke three decades ago.1 Their potential role as key components in flat panel displays and lighting technologies presents the principal driving force behind this growth. Their role in display technologies is particularly promising due to advantages that include efficient power conversion, a wide viewing angle and a good coverage of the colour spectrum.2 Both molecular3 and polymeric species4 are commonly employed as the emissive components in OLEDs. Conjugated polymers suffer distinct disadvantages, such as poor batch-to-batch reproducibility and impurities5 generated during their synthesis that can be challenging to remove. In contrast, small molecules (or oligomers) are monodisperse, can be synthesised with complete reproducibility and, depending on the device fabrication method, can be synthetically tuned to be compatible with either vacuum or solution deposition techniques.6 Furthermore, they can be specifically synthesised to be processable from polar solvents, allowing orthogonal solution-processing to be realised.7,8 Solution processing offers advantages over more established vacuum deposition techniques, such as lower processing costs and more efficient use of material,9 and is thus an auspicious alternative in OLED processing. However, more effort must be made to establish solution-processed methods next to vacuum deposition techniques in industry. To realise this, large-area processing techniques, such as ink-jet or nozzle printing, have been developed to advance the status of solution-processed organic solar cells within the industry for example.10,11

Incorporating phosphorescent heavy metal atoms as dopants within a guest network is a relatively common method for producing red OLEDs. While the metal induces a strong spin-orbit coupling effect and enhances the emission efficiency, such a strategy involves incorporating expensive and finite iridium, ruthenium or europium for example.12 A more recent and increasingly popular strategy utilises the effect of thermally activated delayed fluorescence (TADF) through predominantly increasing use of material,9 and is thus an auspicious alternative in OLED processing. However, more effort must be made to establish solution-processed methods next to vacuum deposition techniques in industry. To realise this, large-area processing techniques, such as ink-jet or nozzle printing, have been developed to advance the status of solution-processed organic solar cells within the industry for example.10,11

Incorporating phosphorescent heavy metal atoms as dopants within a guest network is a relatively common method for producing red OLEDs. While the metal induces a strong spin-orbit coupling effect and enhances the emission efficiency, such a strategy involves incorporating expensive and finite iridium, ruthenium or europium for example.12 A more recent and increasingly popular strategy utilises the effect of thermally activated delayed fluorescence (TADF) through predominantly all-organic systems.13,14 Internal quantum efficiencies of up to 100% are possible, but close control of the energy levels is required to enable thermal up-conversion (reverse intersystem crossing (RISC)) from the triplet to singlet excited states to utilise the TADF effect.15 On the contrary, there are fewer examples of non-doped fluorescent red OLEDs. Such materials are often synthetically straightforward and consist of commonly available

A series of red fluorescent materials (compounds 1–4), which each contain the symmetric fluorene–thiophene–BT–thiophene–fluorene core, is presented along with their performance in solution-processed OLED devices. Extending the molecular conjugation through end-capping with additional fluorene units (compound 2), or through incorporation of donor functionalities (compounds 3 and 4) improves OLED performance relative to the parent compound 1. Notably, incorporating triphenylamine donor groups in compound 3 led to solution-processed OLED devices operating with a peak luminance of 2888 cd m⁻² and a low turn-on voltage (3.6 V).
building blocks. Shimizu and co-workers developed a series of 1,4-bis(diarylamino)-2,5-bis(4-cyano-phenylethenyl) benzenes as novel fluorophores where the emission colour could be finely-tuned by switching the substituents on the diarylamino and cyano-phenyl groups.\textsuperscript{16} Vacuum-processing of these materials into non-doped OLEDs produced deep red emitting devices with external quantum efficiencies (EQE) of 1.36% and a maximum current efficiency of 0.71 cd A\textsuperscript{-1}.\textsuperscript{16} Promarak and co-workers reported the symmetrical molecular emitter CAPTB, consisting of bis(3,6-di-tert-butylcarbazol-9-yl)phenyl aniline end-capping groups attached to a di(thiophen-2-yl)benzothiadiazole fluorescent core, and its role as the emissive layer in a solution-processed, non-doped, fluorescent OLED.\textsuperscript{17} Devices with luminance efficiencies of 1.53 cd A\textsuperscript{-1} were reported, a figure which could be improved significantly to 3.97 cd A\textsuperscript{-1} through inclusion of the electron-injecting/hole-blocking layer dimethyl-4,7-diphenyl-1,10-phenanthroline (BCP). The same authors employed a fluorene–thiophene–BT–thiophene–fluorene core capped with carbazole dendrimers to hinder crystallisation, resulting in OLED devices with a luminance of 4655 cd m\textsuperscript{-2} and a maximum current efficiency of 4.80 cd A\textsuperscript{-1}.\textsuperscript{18} More recently, Ma and co-workers reported a butterfly-shaped donor–acceptor molecule, PTZ–BZP, based on a phenothiazine donor core and benzothiazole acceptor “wings”.\textsuperscript{19} Solution-processed NIR OLEDs offered a high EQE of 1.54% and a maximum brightness of 780 cd m\textsuperscript{-2}. Whilst there was no delayed fluorescence evident, ruling out contributions from TADF for example, the authors proposed a T\textsubscript{1}–S\textsubscript{0} RISC “hot exciton” process as the reason behind the high performance.

Previously, we reported the design, synthesis and application of novel, green emissive molecules that, when solution-processed as the active component in OLEDs, recorded high brightness (maximum luminance = 20 388 cd m\textsuperscript{-2}).\textsuperscript{20} One aspect of these molecules was their straightforward synthesis, which was, in principle, routinely scalable and involved few synthetic steps. This is an important factor when considering the widespread application of functional molecules in organic devices, as lengthy, time-consuming and expensive synthetic pathways are unlikely to attract significant commercial interest. In this work we report the synthesis, characterisation and application of a family of molecular red emitters in solution-processed OLED devices (Fig. 1). Each target contains a common 4,7-di(thiophen-2-yl)benzo[c][1,2,5]thiadiazole core, which is further functionalised with monofluorene or bifluorene units to impart solubility through their alkyl chains.\textsuperscript{21} Compounds 1 (which was mentioned in a patent application in 2012)\textsuperscript{22} and 2 are terminated with a trimethylsilyl functionality (thus enabling halodesilylation\textsuperscript{23}), whilst compounds 3 and 4 are further influenced through additional electron donating groups, consisting of triphenylamine\textsuperscript{24} (compound 3) and benzoferan\textsuperscript{25} (compound 4) units at the terminal ends of the fluorene unit.

**Results and discussion**

**Synthesis**

The strategy for the synthesis of compounds 1 and 2 is represented in Scheme 1. The construction of the common core unit 7 was

![Fig. 1 Structures of the molecular emissive species, compounds 1–4.](image-url)
achieved in two steps: firstly, 4,7-dibromo-2,1,3-benzothiadiazole (5), which was synthesised according to the literature, was coupled with 2-(tributylstannyl)thiophene under Stille conditions to form compound 6. Compound 6 was then brominated in the terminal \( \alpha \)-positions using \( N \)-bromosuccinimide (NBS) to form the key intermediate 7. With this in hand, straightforward Suzuki–Miyaura couplings with the boronic acid functionalised mono- or bifluorene (8 or 9) furnished compounds 1 and 2, respectively. Both reactions proceeded in good yield, giving the target emissive compounds as red powders.

The synthesis of compounds 3 and 4 was somewhat more complex (Scheme 2). Our proposed route involved desilylation of the terminal trimethylsilyl groups in compound 1 for bromine functionalities (compound 10), followed by Suzuki–Miyaura coupling with the appropriately functionalised terminal group. However, it became clear that substitution of the TMS groups of compound 1 to bromines was challenging, with evidence of over-bromination present regardless of the conditions employed as well as residual TMS groups. Alternative reaction pathways involving iododesilylation of the TMS groups were also unsuccessful and led to the formation of by-products. The most successful conditions involved the use of 4.4 equivalents of bromine added to a solution of compound 1 at 0 °C, followed by warming the reaction solution to room temperature overnight. This gave almost quantitative conversion of starting material (97% conversion) with minimal evidence of over-bromination (approximately 6%). As shown in the experimental, exchanging the TMS groups with bromine has no impact on the melting range. The challenging nature of this bromination is in stark contrast to our previous reports using this reaction, indicating that the presence of the additional thiophenes is the likely cause of these complications. With compound 10 in hand, albeit as a mixture, Suzuki–Miyaura coupling with the appropriate electron-rich terminal groups afforded compounds 3 and 4 in yields of 63% and 34%, respectively (Scheme 2).

**Physical characterisation**

All compounds within the series show significant thermal stability, with thermal degradation only observed at temperatures above 360 °C (Table 1). Whilst extending the conjugation increased the thermal stability in compound 2 over monofluorene analogue 1, end-capping with either TPA or benzofuran in compounds 3 and 4 offered even more enhanced stability. TPA-containing compound 3 shows the highest thermal stability with a 5% mass loss temperature of 447 °C. Similarly, end-capping significantly altered the type and temperature of the phase changes observed by differential scanning calorimetry (see Table 1). Compounds 1 and 2 recorded glass transition temperatures of 67 °C and 83 °C, respectively. On the contrary, end-capped analogues 3 and 4 showed no transitions at temperatures below 200 °C indicating an increased suitability for device fabrication.

UV-Vis absorption analysis in dichloromethane showed distinct similarities across the series, with two major absorption bands and a third low intensity peak at higher energies observed for all compounds, which is neglected in the further discussion (Fig. 2). The short wavelength peaks of higher intensity likely correspond to a \( \pi \rightarrow \pi^* \) transition of the excitons, while the lower energy band represents a charge-transfer in which the excited electrons remain on the electron-withdrawing benzothiadiazole core, while the holes are delocalised on the fluorene–thiophene moieties. Whilst there is little difference across the series in the lower energy band, suggesting that increased electron-donating strength has little effect on the absorption characteristics of the core, a more pronounced bathochromic shift is observed in the higher energy
band as the molecular conjugation length is extended in compounds 2–4. Compound 4 offers the largest bathochromic shift compared to compound 1 for the higher energy band, reflecting increased orbital overlap through the planar benzofuran units. On the other hand, the increased donor strength of the TPA groups in compound 3 has a slightly more pronounced effect on the lower energy charge transfer band (Table 1). Similarly, the emission spectra of compounds 1–4 are similar, with one broad band peaking in the range 620–626 nm. The increased donor strength of the TPA units results in the longest wavelength emission maximum of the series for compound 3.

Solid-state PLQY values ranging from 19–33% were recorded for the series, with compound 2 proving to be the most efficient emitter (Table 1).

The effect of extending the conjugation length on the electrochemical behaviour is clear when considering compounds 1 and 2, with a slight increase of the HOMO energy and decrease of the LUMO energy in compound 2 compared to compound 1, resulting in a slight reduction of the electrochemical HOMO–LUMO energy gap (Table 2 and Fig. S1–S4 in the ESI†). Introduction of additional electron-donating groups in compounds 3 and 4 had a subtle effect on the HOMO and LUMO energy levels. Inclusion of the TPA group in compound 3 had no evident effect on the HOMO level compared to compound 1, despite the increase in conjugation length, but reduced the LUMO level to −3.18 eV and the HOMO–LUMO energy gap to 2.06 eV. As observed in the UV-vis absorption spectra, the increased orbital overlap when introducing the planar benzofuran group in compound 4 resulted in a further decrease of the HOMO level to −5.31 eV, while the LUMO level was also reduced when compared to compound 1. However, the overall effect of introducing the benzo[10

a Temperature at which 5% mass loss occurs. b Thermal event recorded by DSC. c Recorded in dichloromethane solution (concentration of 10−5–10−8 M). d Calculated from the onset of the longest wavelength absorbance edge. e Measured from a spin-coated film on a glass substrate at a thickness of 90 nm (±10 nm).
OLED fabrication and characterisation

The performance of an OLED is directly influenced by the thickness of the emissive layer;\textsuperscript{34} defining the optimum thickness early during device optimisation is vital in order to find the balance between a suitably thin active layer for high current, but one that is also thick enough to avoid degradation.\textsuperscript{35} Compound 1 was initially chosen for concentration optimisation using the device configuration ITO/PEDOT:PSS/compound 1/Ca (40 nm)/Al (60 nm), with compound 1 deposited by spin-coating from toluene solution (Table 3). The impact of the turn on voltage on device performance is clear; an increase of 2 V is observed when the thickness of compound 1 is increased. This is due to the concurrent increase in resistance as the active layer thickness increases.\textsuperscript{36} This influences the overall luminance of the device as well, with a concentration of 20 mg ml\textsuperscript{-1} affording an active layer thickness of 90 nm and the highest value for luminance (854 cd m\textsuperscript{-2}). Note that the turn on voltage was recorded when the luminance reached a value of 1 cd m\textsuperscript{-2}.\textsuperscript{35}

Similarly, compounds 2, 3 and 4 were found to provide optimum OLED performance when processed from solutions of 20 mg ml$^{-1}$ concentration, with maximum luminance values of 1561, 1425 and 1498 cd m$^{-2}$, respectively. The higher luminance of compounds 2 and 3 compared with compound 1 can be explained by the higher PLQY (Table 1) values for both compounds compared to the smaller analogue. The extended conjugation present in compounds 2 and 3 recorded a solid state PLQY over 1.5 times higher than compound 1, as shown in Table 3. It is likely that by improving the film morphology, fewer charges were trapped by aggregates, resulting in increased numbers reaching the recombination zone. The higher luminance observed for compound 3 can be explained by a higher current passing through the device, as shown in Fig. 3. Additionally, at approximately 7 V for compound 1 and approximately 8 V for compound 2 the current seems to stabilise around 1000 mA cm$^{-2}$. This saturation phase is not observed in compounds 3 and 4. According to Ohm’s law,$^{37}$ when the voltage is increased, the current should increase proportionally, unless the resistance is changed. For compounds 1 and 2, the resistance of the device increases and the current is limited, while for compounds 3 and 4 no such plateau is evident (Fig. 3).

Compound 4 offered comparable performance with respect to compounds 2 and 3, with a maximum luminance at 1498 cd m$^{-2}$ (similar to the luminance of compound 2) whilst the efficiencies of the OLEDs are close to those fabricated with compound 3. However, its slightly reduced overall performance when compared to these two extended conjugated molecules can be explained by the reduced PLQY of compound 4, which could be caused by increased aggregation quenching, possibly due to the presence of planar benzofuran units. Analysis of atomic force microscopy (AFM) topography images (Fig. S6, ESI$^+$) shows that films containing compound 4 are the roughest and contain the largest domain areas which could be caused by increased aggregation with respect to the other materials.

Fig. 3  Current density and luminance vs. voltage for compounds 1–4.
The effect of thermal annealing on the performance of OLEDs containing compounds 1–4 was studied and in general showed no improvement over untreated devices, with only compound 2 showing a small increase in performance with thermal annealing (Table S1, ESI†). For all other devices the maximum luminance and efficiencies dropped upon thermal annealing. Atomic force microscopy images for films annealed at 80 °C (Fig. S7, ESI†) show that the annealing treatment has little effect on the overall topography with images relatively similar to those for the unannealed films (Fig. S6, ESI†) suggesting that decreased performance with annealing is due to subtle morphological changes. In films containing compound 2 annealing results in the root mean square (RMS) roughness being reduced by 0.15 nm. This small reduction in roughness may explain the improved performance with annealing of compound 2 at temperatures below the glass transition temperature (Tg = 83 °C), despite a relatively similar topography overall.

However, since the saturation phase corresponds almost exactly with the voltage at which the maximum luminance was recorded, the peak performance of both compound 1 and compound 2 has not yet been reached. One factor that may cause this is elevated device temperature, with an increase in heat within the device possibly due to inefficient electron transport in the device compared with the other members of the series. However, the Alq3 layer is also contributing to the emission as devices fabricated with 50 nm of Alq3 produced orange light.

### Conclusion

Herein, a series of four linear, solution-processable red emissive molecules have been reported, all containing a thiophene-benzothiadiazole–thiophene core. The molecules differ through the extent of conjugation and choice of end group functionalisation, which although offering little difference in the physical characteristics of the series, led to significant differences in OLED performance. Compound 3, containing peripheral triphenylamine groups exhibited the highest maximum luminance of 2135 cd m⁻² in addition to a low turn on voltage of 2.3 V when used in a device configuration of ITO/PEDOT:PSS/compound 3/Ca/Al. However, the most efficient OLED in this configuration was produced when compound 2 was the emissive component, leading to an EQE of 0.25%. This trend was consistent when a 50 nm layer of Alq3 led to increased luminance in the compound 3 containing device (2888 cd m⁻²), and highest efficiency when compound 2 was used (0.77%). The dual emission of the red material and green light from Alq3 led to the production of orange light. Such straightforward, readily prepared molecules could be considered as inexpensive fluorescent orange OLEDs for tandem white light devices.

### Experimental

#### General

Tetrakis(triphenylphosphine)palladium(0) [Pd(PPh₃)₄] was prepared prior to use and stored under nitrogen. 4,7-Dibromo-benzothiadiazole and 9,9-diethyl-7-trimethylsilylfluoren-2-yboronic acid and its derivative with two fluorene moieties (compound 8 and 9) were synthesised according to the literature. Unless otherwise stated, all other reagents were sourced commercially and used without further purification. Dry solvents were obtained from a solvent purification system (SPS 400 from
Innovative Technologies) using alumina as the drying agent. 1H and 13C nuclear magnetic resonance (NMR) spectra were recorded on either a Bruker DRX 500 apparatus at 500.13 and 125.76 MHz, or a Bruker Avance DPX400 apparatus at 400.13 and 100.6 MHz. Chemical shifts are given in ppm; all J values are in Hz. Elemental analyses were obtained on a PerkinElmer 2400 analyser. Matrix assisted laser desorption ionisation-time-of-flight (MALDI-TOF) mass spectrometry were run on a Shimadzu Axima-CFR spectrometer (mass range 1–150 000 Da). Thermogravimetric analysis (TGA) was performed using a PerkinElmer Thermogravimetric Analyzer TGA7 under a constant flow of argon. Differential scanning calorimetry (DSC) was recorded on a TA Instruments DSC Q1000 under nitrogen gas. Melting points were taken using a Stuart Scientific Melting Point apparatus. Absorption spectra were recorded on a Shimadzu UV 2700 instrument. Atomic force microscopy studies were carried out using a Bruker Innova AFM and the data was processed using the NanoScope Analysis 1.5 program by Bruker. Photoluminescence measurements were recorded using a PerkinElmer LS 50 B fluorescence spectrometer in a quartz cuvette (path length 10 mm). Absolute PLQY measurements were performed in a calibrated integrating sphere42 attached to an Ocean Optics USB2000+ spectrometer, and a Gooch & Housaux double monochromater with a quartz halogen lamp. The samples were excited at their corresponding longest absorption wavelength. Cyclic voltammetry was recorded on a CH Instruments 660A electrochemical workstation with iR compensation at a scan rate of 100 mV s−1 using anhydrous dichloromethane as the solvent. The electrodes were glassy carbon, platinum wire and silver wire as the working, counter and reference electrodes, respectively. All solutions were degassed (Ar) and contained monomer substrates in concentrations of ca. 10−4 M, together with 0.1 M tetrabutylammonium hexafluorophosphate as the supporting electrolyte. All measurements were referenced against the E1/2 of the Fe/Cc redox couple. The HOMO (LUMO) was calculated by subtracting the half-wave oxidation potential of reduction from −4.8 eV.33

Pre-patterned ITO slides (7 Ω sq−1, 15 mm × 15 mm × 1.1 mm, KINTEC) were cleaned with deionised water, acetone and isopropanol in an ultrasonic bath before treatment with UV–ozone for 2 minutes. This method has been shown to improve the hole injection of ITO and the performance of devices in general.44 For compound 1, a solution concentration of 20 mg ml−1 was found to be optimum and hence used to continue other characterisation measurements such as annealing. These spin-coated films were annealed for 10 minutes at temperatures of 40, 60 and 80 °C. After annealing these films were transferred into a thermal evaporator attached to the glove box for evaporation of the electrodes. An active area of 1.5 × 3.5 mm2 was obtained by evaporation of 40 nm of calcium and 40 nm of aluminium electrodes through a shadow mask at the base pressure of 1 × 10−6 mbar. JVL were measured inside the glove box with a light-tight box attached. A Keithley Semiconductor Characterisation (SCS) 4200 was used to bias the OLEDs. Luminance measurements were performed by using a Macom L203 photometer with a calibrated silicon photodetector and a photopic filter. These calibrations can be traced back to the National Physical Laboratory, London standards. Wavelength dependent electroluminescence spectra were measured by using an Ocean optics USB2000+ spectrometer under a lab atmosphere.

Compound 6. 4,7-Dibromo-2,1,3-benzothiadiazole 5 (750 mg, 2.551 mmol, 1.0 eq.) and tetrakis(triphenylphosphine) palladium(0) (590 mg, 0.510 mmol, 0.2 eq.) were charged to a reaction flask, evacuated and purged with Ar. After anhydrous DMF (10 ml), 2-(tributylstannyl)thiophene (2.43 ml, 7.654 mmol, 3.0 eq.) and anhydrous DMF (5 ml) were added, the mixture was heated to 120 °C and stirred under Ar for 72 h. After this time, the mixture was cooled to r.t., diluted with water (100 ml) and extracted with dichloromethane (3 × 50 ml). The combined organic extracts were washed with brine (100 ml), dried (MgSO4) and concentrated under an orange/brown residue. This residue was dissolved in diethyl ether (50 ml) and washed with water (4 × 80 ml) and brine (100 ml), before being dried (MgSO4) once more and concentrated under vacuum. The resulting orange powder was purified on silica gel, eluting with 20% dichloromethane in hexane, to afford the product (6) as an orange powder (637 mg, 83%); δH (CDCl3, 500.13 MHz) 8.13 (2H, dd, J 3.5, 1.0, ArH), 7.88 (2H, s, ArH), 7.47 (2H, dd, J 5.0, 1.0, ArH), 7.23–7.22 (2H, m, ArH).45 m.p. 120–122 °C, consistent with published data.

Compound 7. Compound 6 (637 mg, 2.12 mmol, 1.0 eq.) was dissolved in chloroform (50 ml) and the reaction flask covered in aluminium foil to ensure the mixture remained dark. N-Bromosuccinimide (831 mg, 4.67 mmol, 2.2 eq.) was added in one portion and the mixture stirred at r.t. under Ar for 72 h. After this time, the reaction mixture was filtered and the resultant orange solid washed with distilled water (20 ml), methanol (150 ml) and chloroform (4 ml). The red powder (7) was dried under vacuum overnight (842 mg, 87%); δH (CDCl3, 400.13 MHz) 7.82 (2H, d, J 4.4, ArH), 7.81 (2H, s, ArH), 7.17 (2H, d, J 4.0, ArH);46 m.p. 252–254 °C, which is consistent with the literature value.47

Compound 1. Compound 7 (300 mg, 0.655 mmol, 1.0 eq.), compound 8 (1.116 g, 2.095 mmol, 3.2 eq.), tetrakis(triphenylphosphine)palladium(0) (151 mg, 0.131 mmol, 0.2 eq.) and barium hydroxide octahydrate (992 mg, 3.144 mmol, 4.8 eq.) were charged to a reaction flask, evacuated and purged with Ar (×3). Anhydrous THF (25 ml) and degassed, distilled water (1.8 ml) were added and the mixture heated to reflux for 40 h. The mixture was then cooled, diluted with water (100 ml), then extracted with dichloromethane (3 × 60 ml). The combined organic extracts were dried (MgSO4) and concentrated under vacuum to a dark orange residue. Silica gel column chromatography, eluting with 10–15% dichloromethane/hexane, afforded the product as a dark purple residue that was dissolved in the minimum volume of hot dichloromethane and precipitated with ice cold methanol. Further cooling in a freezer afforded a dark purple powder that was isolated by filtration. The product (1)
was hence isolated as a deep red powder (525 mg, 72%); δH (CDCl3, 500.13 MHz) 8.17 (2H, d, J 3.5 Hz, ArH), 7.95 (2H, s, ArH), 7.76–7.68 (8H, m, ArH), 7.53–7.49 (6H, m, ArH), 2.06–2.02 (8H, m, CH2), 1.16–1.09 (24H, m, CH2), 0.80–0.72 (20H, m, CH3), 0.34 (18H, s, CH3); δC (CDCl3, 125.76 MHz) 152.7, 151.7, 150.2, 141.4, 140.6, 140.4, 139.8, 139.0, 132.9, 131.9, 128.7, 127.7, 126.2, 126.0, 125.8, 125.3, 124.9, 124.0, 121.5, 120.0, 119.0, 55.4, 55.1, 40.5, 40.1, 31.5, 29.6, 23.7, 22.5, 14.0, –0.9; m/z (MALDI-TOF) 1121.82, m.p. 84–86 °C.

**Compound 2.** Compound 7 (141 mg, 0.308 mmol, 1 eq.), compound 9 (772 mg, 0.986 mmol, 3.2 eq.), tetrakis(triphenylphosphine)palladium(0) (72 mg, 0.062 mmol, 0.2 eq.) and barium hydroxide octahydrate (466 mg, 1.478 mmol, 4.8 eq.) were charged to a reaction flask, evacuated and purged with Ar (3). Anhydrous THF (15 ml) was then added, and the mixture heated to reflux for 40 h. The mixture was then cooled, diluted with water (100 ml), then extracted with dichloromethane (3 × 60 ml). The combined organic extracts were dried (MgSO4) and concentrated under vacuum to a dark orange residue. Silica gel column chromatography, eluting with 10–15% dichloromethane/hexane, afforded a pure product (0.200 g, 63%) after drying in a desiccator; δH (CDCl3, 7 : 3) .

**Compound 3.** Compound 10 was dried in a desiccator overnight. A 50 ml two-neck-flask, a condenser and a 100 ml three-neck-flask were dried in the oven overnight. The condenser was attached to the 50 ml flask, and the glassware was evacuated and refilled with nitrogen three times. The 50 ml flask was then charged with compound 10 (0.249 g, 0.22 mmol, 1 eq.), 4-(diphenylamino)phenylboronic acid (0.204 g, 0.71 mmol, 3.2 eq.), tetrakis(triphenylphosphine)palladium(0) (0.066 g, 0.057 mmol, 0.26 eq.) and barium hydroxide octahydrate (0.349 g, 1.11 mmol, 5 eq.), followed by evacuation and refilling with nitrogen (11.3 x). Then, degassed, anhydrous THF (15 ml) was added, followed by addition of degassed, deionized water (2 ml). The reaction mixture was then stirred for 44 h at 65 °C. After cooling to room temperature, the mixture was poured into 150 ml deionized water. This mixture was then extracted with dichloromethane (50 ml × 3). The solvent was evaporated and the crude product was purified with column chromatography (petroleum ether, 40–60 °C: CHCl3, 7 : 3). Re-precipitation in methanol gave a red solid, which was then washed with acetone, resulting in isolation of the product (3) as an orange solid (0.200 g, 63%) after drying in a desiccator; δH (CDCl3, 400.13 MHz) 8.17 (2H, d, J 3.9 Hz, ArH), 7.96 (2H, s, ArH), 7.78–7.70 (6H, m, ArH), 7.67 (2H, s, ArH), 7.61–7.53 (8H, m, ArH), 7.51 (2H, d, J 3.9 Hz, ArH), 7.28 (8H, t, J 8.3 Hz, ArH), 7.17 (12H, t, J 8.4 Hz, ArH), 7.05 (4H, t, J 7.5 Hz, ArH), 2.06 (8H, m, CH2), 1.19–0.98 (24H, m, CH3), 0.80–0.67 (20H, m, CH2, CH3); δC (CDCl3, 100.76 MHz) 152.8, 152.0, 151.8, 147.8, 147.3, 146.7, 141.0, 139.9, 139.6, 138.5, 135.7, 132.9, 129.4, 128.8, 127.9, 126.0, 125.8, 125.4, 125.0, 124.5, 124.2, 123.1, 120.1, 120.2, 55.5, 40.7, 31.6, 29.8, 24.0, 22.7, 14.2; m/z (MALDI-TOF) 1450.39; HRMS calculated for C100H88N6S4: [M + H]+, 1451.7032. Found: 1451.7015; TGA: 5% mass loss at 447 °C; Tm (DSC) = 241 °C; m.p. 240–242 °C.

**Compound 4.** Compound 10 was dried in a desiccator overnight. A 50 ml two-neck-flask, a condenser and a 100 ml three-neck-flask were dried in the oven overnight and then evacuated and refilled with nitrogen three times. The condenser was attached to the 50 ml two-neck-flask, which was charged with compound 10 (0.292 g, 0.26 mmol, 1 eq.), 2-benzofuranoylboronic acid MIDA ester (0.230 g, 0.84 mmol, 3.2 eq.), tetrakis(triphenylphosphine)-palladium(0) (0.069 g, 0.060 mmol, 0.23 eq.) and barium hydroxide octahydrate (0.401 g, 1.27 mmol, 4.9 eq.). The flask was then evacuated and refilled with nitrogen (×3). Degassed, anhydrous THF (15 ml) and degassed, deionized water (2 ml) were injected, and the mixture was stirred at 65 °C for 44 h.
After cooling to room temperature, the mixture was poured into water (200 ml) and extracted with dichloromethane (50 ml x 3). The crude product was purified twice by column chromatography: the first column used petroleum ether 40–60 °C: CHCl₃ (7:3) as eluent, while the second used petroleum ether 40–60 °C: CHCl₃ (8:2). The product was further purified by re-precipitation in methanol. Following drying in a desiccator, the desired product (4) was isolated as a red powder [0.105 g, 34%]: δ_H (CDCl₃, 400.13 MHz) 8.17 (2H, J 3.9 Hz, ArH), 7.97 (2H, J 8.2 Hz, ArH), 7.76–7.72 (4H, m, ArH), 7.69 (2H, s, ArH), 7.61 (2H, J 7.6 Hz, ArH), 7.58 (2H, J 8.1 Hz, ArH), 7.54 (2H, d, J 3.9 Hz, ArH), 7.31 (2H, td, J 15.2, 7.0, 1.2 Hz, ArH), 7.25, 7.12 (2H, s, ArH), 2.10 (8H, m, CH₂), 1.91–1.01 (24H, m, CH₂), 0.75 (12H, J 6.97 Hz, CH₃), 0.68 (8H, m, CH₂); δ_C (CDCl₃, 100.76 MHz) 156.7, 155.1, 152.8, 152.1, 151.8, 146.5, 141.3, 140.7, 138.6, 133.3, 129.6, 129.5, 128.8, 125.9, 125.5, 125.1, 124.3, 124.3, 124.2, 123.1, 120.9, 120.5, 120.3, 120.2, 119.3, 111.3, 101.4, 55.6, 40.6, 31.6, 29.8, 24.0, 22.6, 14.2; m/z (MALDI-TOF) 1196.15; HRMS calculated for C₈₀H₈₀N₂O₂S₃: (M + H)⁺, 1197.5450; TGA: 5% mass loss at 408 °C; T_m (DSC) = 224 °C, m.p. 232–234 °C.
