Abstract—Millimeter-wave (mmWave) massive multiple input multiple input, multiple output (MIMO) has shown great potential in user equipment (UE) localization of 5G wireless communication systems. However, mmWave signals usually suffer from non-line-of-sight (NLOS) propagation, which will affect mmWave MIMO-based UE localization performance. Hence, it is non-trivial to reveal how NLOS propagation affect mmWave-based UE localization performance. In this paper, we give a unified analysis framework for UE localization performance gain from harnessing NLOS propagation. Firstly, a closed-form Cramer-Rao lower bound on mmWave MIMO-based UE localization is derived to shed lights on its performance limit. Secondly, NLOS propagation-caused localization error for conventional UE localization methods without harnessing multipath effect is analysed. Finally, the information contribution from NLOS channel is quantified, which sheds light on how to smartly harness NLOS propagation and the associated UE localization performance gain.

Index Terms—Localization, 5G mmWave MIMO, Cramer-Rao lower bound, performance limits, non-line-of-sight propagation.

I. INTRODUCTION

MASSIVE multi-input multi-output (MIMO) mmWave-based localization has received much attention, due to the expected rising demands of localization-aware services in the future [1]–[3]. It is shown in [4] that mmWave MIMO system can provide a high-resolution positioning solution approaching subcentimeters accuracy for user equipments (UEs). A number of papers, for example [4]–[10], have investigated UE localization for mmWave MIMO systems.

In practice, mmWave signals suffer from diffuse scattering, which will affect the performance of mmWave MIMO-based UE localization. Conventional localization approaches treat non-line-of-sight (NLOS) paths as disturbance sources without any information contribution to UE localization, due to complex diffuse-scattering models. Hence, only the line-of-sight (LOS) channel is employed to extract UE location knowledge. Hence, their localization performance will be affected by the NLOS propagation. However, the localization performance gain from harnessing NLOS paths is not studied.

Performance limits of mmWave MIMO-based UE localization are reported by a few research works, e.g., [4], [11]–[13]. In [4], a Cramer-Rao lower bound (CRLB) on the two-dimensional UE localization error is derived, and [12] extends this CRLB analysis to a three-dimensional regime. In [11], the localization performance using a single array is studied. In spite of their great efforts, the effect of NLOS propagation on UE localization is not investigated. Thus, a comprehensive understanding on the performance limits of mmWave MIMO-based UE localization over multipath propagation is needed.

In this paper, we aim to provide a unified analysis framework for mmWave MIMO-based UE localization performance, which is challenging due to the complex scattering model and small-scale channel fading. UE localization performance gain from harnessing NLOS propagation is quantitatively analysed, which sheds lights on the performance limits of mmWave MIMO-based UE localization over NLOS propagation. It is shown that it is possible to mitigate the NLOS effect by a carefully-designed localization algorithm.

The remainder of this paper is organized as follows. Section II presents the system model. The impact of the NLOS propagation is analysed in Section III. Simulation results are given in Section IV. Finally, Section V concludes the paper.

II. SYSTEM MODEL

In this section, we elaborate the system setup and channel model for mmWave-based UE localization.

A. System Setup

We consider a mmWave system with \( J \) base stations (BSs), one UE and \( N'_U \) subcarriers. Each BS has \( N_B \) antennas, whereas the UE has \( N_U \) antennas, as shown in Fig. 1. BSs will transmit pilots for estimating UE location parameters.

We consider OFDM signaling and the length of cyclic prefix exceeds the maximum delay. We assume small-scale fading coefficients to be invariant within each time slot. Each time slot consists of a number of symbols, where the first \( M \) symbols are used to transmit pilots, and the rest are used to transmit data. In addition, \( N'_U \) subcarriers of each pilot are fairly allocated to those \( J \) BS’s via some predefined scheduling procedure, and

This work was supported by National Natural Science Foundation of China under Grant 62001526, and in part by the Natural Science Foundation of Guangdong Province under Grant 2021A1515012021.
where the ULA steering matrix of the jth BS on the nth subcarrier, which has absorbed the beamforming (BF) matrix and pilots. For brevity, let \( \omega \in \mathbb{C}^{N_0 \times NC + M} = \text{vec}[\omega_j[n, m]]\forall n = 1 : NC, \forall m = 1 : M, \forall j = 1 : J \) be the collection of pilot vectors, which are unknown scalars. For each NLOS path, there is a \( \tau_{l,j} \) and \( \omega_{l,j} \) which have absorbed the beamforming (BF) matrix and pilots.

### C. Received Signal Model

Let \( z_j[n, m, k] \in \mathbb{C}^{N_0} \) be the observation signal, i.e., the \( m \)th received pilot signal vector on subcarrier \( n \) from the \( j \)th BS at the \( k \)th time slot, which is given by [4]

\[
z_j[n, m, k] = \mathbf{H}_j[n, k] \omega_j[n, m] + e_j[n, m, k],
\]

where \( e_j[n, m, k] \in \mathbb{C}^{N_0} \) is the measurement noise vector. Let \( z[k] \in \mathbb{C}^{N_0 \times NC + M} = \text{vec}[z_j[n, m, k]]\forall n = 1 : NC, \forall j = 1 : J \) and \( e[k] \in \mathbb{C}^{N_0 \times NC + M} = \text{vec}[e_j[n, m, k]]\forall n = 1 : NC, \forall j = 1 : J \) be the collection of received signals and noises, respectively. Let \( \mathbf{\alpha} \in \mathbb{R}^{3} = [\mathbf{x}^T, \theta]^T \) be UE location parameter, and let \( v \in \mathbb{R}^{2JL} = \text{vec}[v_{l,j}]|\forall l = 1 : L, \forall j = 1 : J \) be the collection of scatterer locations.

Then, \( z[k] \) is a function of \( \mathbf{\alpha}, \mathbf{h}[k] \) and \( e[k] \), given by

\[
z[k] = \mathbf{g}(\mathbf{\alpha}, \mathbf{v}, \mathbf{h}[k]) + e[k],
\]

where we assume \( e \sim \mathcal{N}(0, \sigma^2 \mathbf{I}_{NC \times M}) \) with variance \( \sigma^2 \), \( \mathbf{I}_{NC \times M} \) is an \( NC \times M \)-dimensional identity matrix, and \( \mathbf{g}(\mathbf{\alpha}, \mathbf{\nu}, \mathbf{h}[k]) \) is given by

\[
\mathbf{g}(\mathbf{\alpha}, \mathbf{v}, \mathbf{h}[k]) = \mathbf{G}(\mathbf{\alpha}, \mathbf{v})\mathbf{h}[k],
\]

in which \( \mathbf{G}(\mathbf{\alpha}, \mathbf{\nu}) \in \mathbb{C}^{NC \times M(j+1)} \) is called the coefficient matrix of channel vector \( \mathbf{h}[k] \), that is dependent on the
unknown location parameter $\alpha$ and is given by [4]

$$\mathbf{G}(\alpha, \mathbf{v}) = \text{diag}[(\mathbf{G}_j)_{\forall j=1:J}], \quad (14)$$

$$\mathbf{G}_j \in \mathbb{C}^{N_t \times M_{\times (L+1)}} = \text{vec}[(\mathbf{g}_j^{(r)})_{n,m}^{(r)}]_{\forall r, \forall n, \forall m}, \quad (15)$$

$$\mathbf{g}_j^{(r)}[n,m] \in \mathbb{C}^{L+1} = \text{vec}[(\mathbf{g}_j^{(r)})_{n,m}^{(r)}], \quad (16)$$

$$\mu_{j,n}^{(r)}[n,m] = \sqrt{N_t} \mathbf{U}_j^\top [n,m] \mathbf{\mu}^{(r)}_{j,n}, \quad (17)$$

$$\mu_{j,n}^{(r)} \in \mathbb{C}^{N_a} = \text{vec}[(\mathbf{\mu}^{(r)}_{j,n})_{n,m}^{(r)}], \quad (18)$$

$$\mu_{j,n}^{(r)}(\theta_{U,t,j}) = \alpha_{n}^{(r)}(\theta_{U,t,j})e^{-j2\pi \frac{\pi c}{\lambda} n r \tau_j} (a_{n}^{(t)}(\theta_{B,t,j}))^* \tau_l \in \mathbb{C}^{2}, \quad (19)$$

where $\alpha_{n}^{(r)}(\theta_{U,t,j})$ and $a_{n}^{(t)}(\theta_{B,t,j})$ is the $r$th and the $t$th element of $\mathbf{a}_{U,n}(\theta_{U,t,j})$ and $\mathbf{a}_{B,n}(\theta_{B,t,j})$ in (4) and (2), respectively. It should be noted that $\alpha_{n}^{(r)}(\theta_{U,t,j})$ and $a_{n}^{(t)}(\theta_{B,t,j})$ are functions of location parameters $\mathbf{x}$, $\vartheta$, and $\mathbf{v}_{i,j}$ via (5)-(10).

III. THE EFFECT OF NLOS PROPAGATION

In this section, we analyse UE localization performance to understand the effect of NLOS propagation on UE localization.

A. UE Localization Method

We consider two UE localization methods, and both extract UE location knowledge from the LOS path only. The difference between these two methods lies in the treatment of NLOS paths: in the first-type LOS channel-based localization method, the NLOS paths are viewed as the disturbance source; while in the second-type LOS channel-based localization method, the NLOS channel state is treated as unknown parameters to be jointly estimated along with UE localization.

For convenience, let $\mathbf{h}_{\text{LOS}}[k] = \text{vec}[\mathbf{h}_j[k]_{\forall j=1:J}] \in \mathbb{C}^{J}$ and $\mathbf{h}_{\text{NLOS}}[k] = \text{vec}[\mathbf{h}_j[k]_{\forall l=1:L, \forall j=1:J}] \in \mathbb{C}^{JL}$ denote the small-scale fading coefficient vector associated with the LOS channel and the NLOS channel, respectively.

1) First-Type LOS Channel-Based Localization Approach: This UE localization estimates $\alpha$ via exploiting LOS propagation knowledge, where unknown NLOS paths are treated as disturbance sources without any information constraint. It is formulated as

$$\mathcal{B}_{\text{LOS}}^{(1)} : \hat{\alpha}_{\text{LOS}}^{(1)} = \arg \min_{\alpha} \mathbb{E}_{\mathbf{h}_{\text{LOS}}}[||z[k] - g_{\text{LOS}}(\alpha, \mathbf{h}_{\text{LOS}}[k])||^2_2], \quad (20)$$

where $g_{\text{LOS}}(\alpha, \mathbf{h}_{\text{LOS}}[k]) \in \mathbb{C}^{N_t \times N_t M_{\times J}}$ is the LOS component of the measurement signal, given by

$$g_{\text{LOS}}(\alpha, \mathbf{h}_{\text{LOS}}[k]) = \mathbf{G}_{\text{LOS}(\alpha)} \mathbf{h}_{\text{LOS}}[k], \quad (21)$$

and $\mathbf{G}_{\text{LOS}(\alpha)} \in \mathbb{C}^{N_t \times N_t M_{\times J \times J}}$ is the coefficient matrix of LOS channel coefficient vector $\mathbf{h}_{\text{LOS}}[k]$, given by

$$\mathbf{G}_{\text{LOS}(\alpha)} = \text{diag}[(\mathbf{g}_j)_{\forall j=1:J}], \quad (22)$$

$$\mathbf{g}_j = \text{vec}[(\mathbf{g}_j^{(r)})_{n,m}^{(r)}]_{\forall r, \forall n, \forall m}, \quad (23)$$

where $\mathbf{g}_j^{(r)}[n,m]$ is given by (17). Given $\alpha_{n}^{(r)}$, LOS channel estimate $\mathbf{h}_{\text{LOS}}[k]$ can be obtained using the linear least square estimation, as per the linear model (21). $\mathcal{B}_{\text{LOS}}^{(1)}$ is non-convex w.r.t. the UE location parameter due to the nonlinear cost function in $\alpha$. This LOS channel-based localization covers a number of conventional UE localization methods, for instance, TOA-based localization [14] and trilateration-based localization method.

2) Second-Type LOS Channel-Based Localization Method: This method jointly estimates UE location parameters (using the LOS path) and NLOS channel states which absorb small-scale fading coefficients, BS steering gain, UE response gain and time-delay-caused phase shift.

Let $\mathbf{c}_{j,n}^{(r)}[k] = \mathbf{a}_{n}^{(r)}(\theta_{U,t,j}) \mathbf{h}_{j,n}^{(r)}[k] \mu_{j,n}^{(r)}(\theta_{B,t,j})$ denote the overall NLOS channel associated with the $(r,t)$th receiver-transmitter antenna pair of the $j$th BS at the $n$th subcarrier and the $k$th time slot, for the $t$th NLOS path. For convenience, we use the following notations,

$$\mathbf{c}_{j,n}^{(r)}[k] = \mathbf{c}_{j,n}^{(r)}[k]_{\forall l=1:L} \in \mathbb{C}^{L}, \quad (24)$$

$$\mathbf{h}_{\text{NLOS}}^{\text{EQ}}[k] = \text{vec}[(\mathbf{c}_{j,n}^{(r)}[k])_{\forall t, \forall n, \forall m, \forall j}], \quad (25)$$

where $\mathbf{h}_{\text{NLOS}}^{\text{EQ}}[k] \in \mathbb{C}^{L J M N_t N_a}$ denotes the NLOS channel vector. Let $\mathbf{h}_{\text{EQ}}[k] \in \mathbb{C}^{J+LM N_t N_a} = [\mathbf{h}_{\text{LOS}}[k] \mid \mathbf{h}_{\text{NLOS}}^{\text{EQ}}[k]]$ be the equivalent channel. Let $\chi[k] \in \mathbb{C}^{J+LM N_t N_a}$ be the overall variable. Specifically, the second-type LOS channel-based localization method is formulated as

$$\mathcal{B}_{\text{LOS}}^{(2)} : \chi_{\text{LOS}}^{(2)} = \arg \min_{\chi[k]} ||z[k] - g_{\text{EQ}}(\chi[k])||^2_2, \quad (26)$$

where the measurement function $g_{\text{EQ}}(\chi[k])$ is reformulated as

$$g_{\text{EQ}}(\chi[k]) = g_{\text{LOS}}(\alpha, \mathbf{h}_{\text{LOS}}[k]) + \mathbf{W}^\dagger \mathbf{h}_{\text{NLOS}}^{\text{EQ}}[k], \quad (27)$$

where $g_{\text{LOS}}(\alpha, \mathbf{h}_{\text{LOS}}[k])$ relates to the LOS path, given by (21), and $\mathbf{W} \in \mathbb{C}^{L J M N_t N_a \times J M N_t N_a}$ denotes the known pilot symbol matrix, given by

$$\mathbf{W} = \text{diag}[(\mathbf{W}_j)_{n,m}^{(r)}]_{\forall n, \forall m, \forall j}, \quad (28)$$

$$\mathbf{W}_j[n,m] \in \mathbb{C}^{N_t N_a L \times N_t L} = \mathbf{I}_{N_t} \otimes \mathbf{w}_j[n,m], \quad (29)$$

$$\mathbf{w}_j[n,m] \in \mathbb{C}^{N_t L} = \mathbf{1}_L \otimes \mathbf{w}_j[n,m], \quad (30)$$

in which $\mathbf{1}_L$ is an $L$-dimensional all-one vector.

B. UE Localization Performance

We shall explicate the closed-form CRBL for the above two typical LOS channel-based localization methods to reveal the UE location information from the LOS channel.

1) First-Type LOS Channel-Based Localization Error: For $\mathcal{B}_{\text{LOS}}^{(1)}$, since NLOS paths are treated as disturbances, there are two error sources, i.e., unknown NLOS signals and measurement noise. The unknown NLOS signal will lead to a fixed localization error for a certain measurement signal, since the small-scale fading coefficients of NLOS paths are assumed to be invariant within a time slot and the UE location is fixed. Hence, the NLOS paths will lead to a certain localization bias, instead of a “random localization error”. In contrast, measurement noises will lead to a random localization error, which can be bounded by its CRBL.

We give a theorem to bound the error of the first-type LOS channel-based UE localization problem $\mathcal{B}_{\text{LOS}}^{(1)}$. 
Theorem 1 (First-Type LOS Channel-Based UE Localization Error): The mean squared error of the first-type LOS channel-based localization problem is bounded as follows,
\[
\mathbb{E}\{\|\hat{\alpha}^{(1)}_{\text{LOS}} - \alpha\|_2^2\} \geq \text{trace}\left( \mathbf{B}^{(1)}_{\alpha}(\alpha) + \Omega_\alpha \right),
\]  
(31)

where \(\hat{\alpha}^{(1)}_{\text{LOS}}\) is the UE location estimate as per \(\mathcal{S}^{(1)}_{\text{LOS}}\), \(\Omega_\alpha \in \mathbb{S}^3 = \{\mathbb{E}\{\hat{\alpha}^{(1)}_{\text{LOS}}\} - \alpha\} \{\mathbb{E}\{\hat{\alpha}^{(1)}_{\text{LOS}}\} - \alpha\}^\top\) is the NLOS path-caused UE location estimate bias, and \(\mathbf{B}^{(1)}_{\alpha}(\alpha)\) is the CRLB on the unbiased UE location error, given by
\[
\mathbf{B}^{(1)}_{\alpha}(\alpha) = \left( \sigma^{-2} \mathbf{D}_{\text{LOS}} \mathbf{H}_{\text{LOS}}[k] \Psi_{\text{LOS}} \mathbf{H}^H_{\text{LOS}}[k] \mathbf{D}^H_{\text{LOS}} \right)^{-1},
\]  
(32)

where \(\mathbf{D}_{\text{LOS}} \in \mathbb{C}^{J \times J M N C N U}\) is given by (45), and \(\mathbf{H}_{\text{LOS}}[k] \in \mathbb{C}^{J M N C N U \times J M N C N U}\) is given by
\[
\mathbf{H}_{\text{LOS}}[k] = \text{diag}\{\mathbf{H}^{\text{LOS}}_j[k]\} \{\mathbf{H}^{\text{LOS}}_j[k]\}^\top \in \mathbb{C}^{J \times J},
\]  
(33)

in which \(\mathbf{H}^{\text{LOS}}_j[k] \in \mathbb{C}^{M N C N U \times M N C N U}\) is given by
\[
\mathbf{H}^{\text{LOS}}_j[k] = \mathbf{I}_{M N C N U} \otimes \mathbf{h}_{0,j}[k],
\]  
(34)

and \(\Psi_{\text{LOS}} \in \mathbb{S}^{J M N C N U}\) is given by
\[
\Psi_{\text{LOS}} = \mathbf{I}_{J M N C N U} - \mathbf{G}_{\text{LOS}} \mathbf{C}_{\text{LOS}}^{-1} \mathbf{G}^H_{\text{LOS}},
\]  
(35)

where \(\mathbf{G}_{\text{LOS}} \in \mathbb{C}^{J N C N U \times J}\) is given by (22).

Proof: See the proof in APPENDIX A. □

The first-type LOS channel-based location Fisher information matrix (FIM) \(\mathcal{J}^{(1)}_{\alpha}(\alpha)\) in (32) quantifies the UE location information from the LOS channel. It is difficult to establish the closed-form expression of UE location estimate bias \(\Omega_\alpha\) due to complex system models. However, the above closed-form CRLB is still meaningful for bounding the achieved UE localization error of \(\mathcal{S}^{(1)}_{\text{LOS}}\). To address this challenge, in the following, we aim to approximately characterize the NLOS-path-caused UE location estimate bias.

For ease of notation, let \(\varepsilon_\alpha = (\text{trace}(\Omega_\alpha))^{\frac{1}{2}}\) be the location bias in meters, and let \(\mathbf{g}_{\text{NLOS}}[k] \in \mathbb{C}^{J M N C N U}\) be the LOS path of the first-type LOS channel-based localization method, as shown in (27).

Theorem 2 (NLOS-Caused Localization Bias): The LOS path-caused UE location estimate bias \(\varepsilon_\alpha\) in the first-type LOS channel-based localization method is given by
\[
\varepsilon_\alpha = \|\mathbf{g}_{\text{NLOS}}[k]\|_2 \|\mathbf{D}_{\text{LOS}}[k] \mathbf{H}_{\text{LOS}}[k]\|_2^{-1} + \alpha_\alpha,
\]  
(36)

where \(\alpha_\alpha\) is a second-order infinitesimal which can be safely ignored, i.e., \(\alpha_\alpha \sim \mathcal{O}\left(\|\hat{\alpha}^{(1)}_{\text{LOS}} - \alpha\|_2^2 + \|\mathbf{h}^{(1)}_{\text{LOS}}[k] - \mathbf{h}_{\text{LOS}}[k]\|_2^2\right)\).

Proof: See APPENDIX B. □

Remark 1 (NLOS Path-Caused Location Error Floor): It is shown in Theorem 1 that the UE location error bound \(\mathbf{B}^{(1)}_{\alpha}(\alpha)\) of the first-type LOS channel-based localization method is proportional to the measurement noise variance \(\sigma^2\). In addition, the NLOS-path-caused UE location bias \(\varepsilon_\alpha\) is invariant with \(\sigma^2\). Hence, as the SNR increases, the first-type LOS channel-based localization error will gradually reduce and finally hit an error floor \(\varepsilon_\alpha\) due to NLOS propagation. Hence, in the high SNR region, the unknown NLOS path will become the dominant error source, which limits the performance of the first-type LOS channel-based localization method. □

Corollary 1 (Scaling of LOS Channel-Based Localization Bias): The first-type LOS channel-based UE localization error scales with the NLOS signal strength in the following manner:
\[
\lim_{\|\mathbf{g}_{\text{NLOS}}[k]\|_2 \to 0} \frac{\varepsilon_\alpha}{\|\mathbf{g}_{\text{NLOS}}[k]\|_2} = \|\mathbf{D}_{\text{LOS}} \mathbf{H}_{\text{LOS}}[k]\|_2^{-1},
\]  
(37)

where \(\|\cdot\|_2\) denotes the \(\ell_2\)-norm on a matrix.

Proof 1: It directly follows from Theorem 2.

Remark 2: It is shown that the NLOS-caused UE location error floor vanishes as the NLOS signal strength tends to zero. In addition, this location error floor is affected by the LOS channel quantity, i.e., the LOS channel gain \(\mathbf{h}_{\text{LOS}}[k]\). □

The above conclusions are applied to conventional TOA-based localization methods in which it is well known that NLOS paths will lead to a localization bias.

2) Second-Type LOS Channel-Based Localization CRLB: We give a theorem to establish the closed-form CRLB for the second-type LOS channel-based localization method.

Theorem 3 (Second-Type LOS Channel-Based UE Location CRLB): For an unbiased UE location estimate \(\hat{\alpha}^{(2)}_{\text{LOS}}\) of the second-type LOS Channel-based localization problem \(\mathcal{S}^{(2)}_{\text{LOS}}\), its mean squared error is bounded as
\[
\mathbb{E}\{\|\hat{\alpha}^{(2)}_{\text{LOS}} - \alpha\|_2^2\} \geq \text{trace}\left( \mathbf{B}^{(2)}_{\alpha}(\chi[k]) \right),
\]  
(38)

where \(\mathbf{B}^{(2)}_{\alpha}(\chi[k])\) is the associated CRLB given by
\[
\mathbf{B}^{(2)}_{\alpha}(\chi[k]) = \left( \sigma^{-2} \mathbf{D}_{\text{LOS}} \mathbf{H}_{\text{LOS}}[k] \mathbf{A} \mathbf{H}^H_{\text{LOS}}[k] \mathbf{D}^H_{\text{LOS}} \right)^{-1},
\]  
(39)

where \(\mathbf{D}_{\text{LOS}}\) is given by (45), \(\mathbf{A} \in \mathbb{C}^{J M N C N U} = \mathbf{I}_{J M N C N U} - \mathbf{W}^H (\mathbf{W}^H)^\top \mathbf{W}, \) and \(\mathbf{W} \in \mathbb{C}^{(J M N C N U + J) \times J M N C N U}\) is given by
\[
\mathbf{W} = [\mathbf{H}^H_{\text{LOS}}, \mathbf{W}].
\]  
(40)

Proof: See the proof in APPENDIX C. □

Remark 3: The associated FIM \(\mathcal{J}^{(2)}_{\alpha}(\chi[k])\) quantifies the UE location information from the LOS channel and the estimate of NLOS channel states, which essentially depends on BS locations, SNR, channel gain, base station BF directions, and the size of BS/UE antenna arrays. Specifically, the second-type LOS channel-based UE localization CRLB \(\text{trace}(\mathbf{B}^{(2)}_{\alpha}(\chi[k]))\) is proportional to the noise variance \(\sigma^2\) and hence the inverse of the SNR. This means that the NLOS propagation-caused UE location error floor in the high SNR region is vanished in the second-type LOS channel-based localization method due to the joint estimate of NLOS channel coefficients, which is different from the first-type LOS channel-based localization method. The second-type LOS channel-based localization provides a promising solution to mmWave MIMO-based UE localization. □
C. Gain from Exploiting NLOS Paths

It should be noted that, in those two LOS channel-based localization methods $\mathcal{P}_\text{LOS}^{(I)}$ and $\mathcal{P}_\text{LOS}^{(II)}$, UE location information is extracted from the LOS channel only. Yet, unlike $\mathcal{P}_\text{LOS}^{(I)}$, the second-type localization method $\mathcal{P}_\text{LOS}^{(II)}$ does not have NLOS-caused localization error floor $\varepsilon_\text{P}^{(II)}$, due to the joint estimate of NLOS channel state $\mathbf{h}_{\text{NLOS}}^{(I)}[k]$. The performance gain of the second-type LOS channel-based localization from NLOS channel estimate is revealed below.

Remark 4 (Performance Gain of LOS Channel-Based Localization from NLOS Channel Estimate): Compared with $\mathcal{P}_\text{LOS}^{(I)}$, the performance gain of the second-type localization method $\mathcal{P}_\text{LOS}^{(II)}$ from NLOS channel estimate is given by $\mathcal{Q}_\text{P}^{(II)} - \mathcal{P}_\text{P}^{(II)} = \sigma^2 \left( \mathbf{D}_{\text{LOS}} \mathbf{H}_{\text{LOS}}[k] \left( \mathbf{V}_{\text{LOS}}^{-1} - \mathbf{L}^{-1} \mathbf{H}_{\text{LOS}}^\mathsf{H}[k] \mathbf{D}_{\text{LOS}}^\mathsf{H} \right)^{-1} + \mathbf{Q}_{\text{P}}^{(II)} \right) - \mathcal{Q}_\text{P}^{(I)} - \mathcal{P}_\text{P}^{(I)}$.

This can be easily verified by combining (32) and (39).

IV. NUMERICAL RESULTS

We shall give numerical results to verify the performance limits of various localization methods.

A. Simulation Settings

We set the number of base stations to $J = 3$ and each BS has $N_C = 10$ subcarriers. We set $L = 2$, $M = 10$, $N_B = N_U = 16$, carrier frequency $f_c = 60$ GHz, sampling period $T_s = 10$ ns (i.e., the bandwidth is 100 MHz) and the speed of light $c = 3 \times 10^8$ m/s. We set $\text{SNR} = 10$ dB, unless specified otherwise, where $\text{SNR} = \frac{\mathbb{E}\{||\mathbf{g}_Q(\mathbf{x}[k])||_2^2\}}{\mathbb{E}\{||\mathbf{e}[k]||_2^2\}}$.

Based on these parameters, $\lambda_n$ and $d_A$ can be determined via $\lambda_n = \frac{c}{N_CN_T f_c}$ and $d_A = c/f_c/2$, respectively. We assume a simple path loss model for each channel, i.e., $h_{l,j} = \frac{1}{N_{l,j}}$, where $\lambda_{l,j}$ is the length of the path and $h_{l,j}^* \sim \mathcal{N}_C(0, 1)$ is the small-scale fading. Locations of UE and BSs are random within a squared area of $50 \times 50 \text{ m}^2$, and their orientation angles are also random. In addition, the transmitted pilot signal $\omega_j[n, m]$ is set to be uniformly distributed on the unit circle, unless specified otherwise.

B. Simulation Results

1) The Impact of NLOS Propagation: The UE localization error vs. the number of NLOS paths is shown in Fig. 2 and Fig. 3. It is shown that the first-type LOS paths lead to a larger error for the first-type LOS channel-based localization method. In contrast, for the second-type LOS channel-based localization method, its performance is almost not affected by the number of NLOS paths. This means that this localization method can achieve a reliable solution in scattering environments, due to the joint estimate of NLOS channel state.

2) The Effect of SNR: UE location and orientation error performance vs. SNR are presented in Fig. 4 and 5, respectively. It is shown that the first-type LOS channel-based localization method will hit an error floor due to the NLOS propagation as the SNR increases. This is because the NLOS propagation will become the dominant error source for this localization method when $\text{SNR} > 10$ dB. Moreover, the second-type LOS channel-based localization error decreases to zero as the SNR increases. In other words, this method breaks the NLOS propagation-caused error floor in the high SNR region due to the exploitation of NLOS channels.

V. CONCLUSIONS

In this paper, the UE localization performance limits over multipath propagation and small-scale fading are studied for 5G mmWave MIMO systems. The closed-form CRLBs for the UE localization and the channel estimate, respectively, are obtained. The UE localization performance gain from harnessing NLOS propagation is revealed. It is shown that the UE localization error will be significantly reduced by carefully designing a NLOS propagation harnessing scheme, particularly in a high SNR environment.
E{(α\textsubscript{LOS} - α)(α\textsubscript{LOS} - α\textsuperscript{T})} = \Omega_α + E{(α\textsubscript{LOS} - E(α\textsubscript{LOS}))(α\textsubscript{LOS} - E(α\textsubscript{LOS})). (41)

APPENDIX B
PROOF OF THEOREM 2

Let \alpha\textsubscript{true} and \hat{h}\textsubscript{LOS}[k] be the true value of \alpha and \hat{h}\textsubscript{LOS}[k], respectively. As per (12), we have \[ z[k] = g\textsubscript{LOS}(\alpha, h\textsubscript{LOS}[k]) + gnLOS + \epsilon[k], \]

where \[ g\textsubscript{LOS}[k] \]

stands for the unknown NLOS component and \[ g\textsubscript{LOS}(\alpha, h\textsubscript{LOS}[k]) = G\textsubscript{LOS}(\alpha)h\textsubscript{LOS}[k]. \]

Let \[ (\alpha\textsubscript{LOS}[k], h\textsubscript{LOS}[k]) \]

be the biased estimate from \[ z[k]. \]

Hence, we have \[ G\textsubscript{LOS}(\alpha\textsubscript{LOS}[k], h\textsubscript{LOS}[k]) = G\textsubscript{LOS}(\alpha\textsubscript{true}, h\textsubscript{true}\textsubscript{LOS}[k]). \]

By applying the first-order expansion to \[ G\textsubscript{LOS}(\alpha\textsubscript{LOS}[k]) \]

around \[ (\alpha, h\textsubscript{LOS}[k]) = (\alpha\textsubscript{true}, h\textsubscript{true}\textsubscript{LOS}[k]), \]

we have

\[ G\textsubscript{LOS}(\alpha\textsubscript{LOS}[k]) \]

\[ = G\textsubscript{LOS}(\alpha\textsubscript{true}, h\textsubscript{true}\textsubscript{LOS}[k]) \]

\[ + \left[ \nabla_\alpha (G\textsubscript{LOS}(\alpha\textsubscript{true}, h\textsubscript{true}\textsubscript{LOS}[k]) \right]\]

\[ \cdot (\alpha\textsubscript{LOS}[k] - \alpha\textsubscript{true}) \]

\[ + O(||\alpha\textsubscript{LOS}[k] - \alpha\textsubscript{true}\|_2^2 + ||h\textsubscript{LOS}[k] - h\textsubscript{true}\textsubscript{LOS}[k]\|_2^2). \]

Hence, by ignoring the high-order infinitesimal term and taking the expectation over \[ \epsilon, \]

we have

\[ \left[ \nabla_\alpha (G\textsubscript{LOS}(\alpha\textsubscript{true}, h\textsubscript{true}\textsubscript{LOS}[k]) \right]\]

\[ \cdot E(\alpha\textsubscript{LOS}[k] - \alpha\textsubscript{true}) \]

\[ \approx G\textsubscript{LOS}(\alpha\textsubscript{true})h\textsubscript{true}\textsubscript{LOS}[k]. \]

\[ \text{gnLOS, where we have considered that } E(\epsilon) = 0. \]

As a result, we arrive at (51).

We know that \[ \nabla_\alpha (G\textsubscript{LOS}(\alpha\textsubscript{true}, h\textsubscript{true}\textsubscript{LOS}[k]) = D\textsubscript{LOS}H\textsubscript{LOS}[k] \]

and \[ \epsilon\alpha = ||E(\alpha\textsubscript{LOS}[k] - \alpha\textsubscript{true}||_2. \]

Hence, taking the trace of the \[ 3 \times 3 \]

left-top submatrix and the \[ 3 \times 3 \]

right-bottom submatrix of the correlation matrix \[ g\textsubscript{LOS}[k] \]

in (51), respectively, and using the singular-value-decomposition of the left coefficient matrix, Theorem 2 is proved.

APPENDIX C
PROOF OF THEOREM 3

Based on the second-type LOS channel-based localization model in (26) and (27) and as per the FIM definition in (43),
\[ J^{(l)}_{\beta_{\text{LOS}}[k]}(\beta_{\text{LOS}}[k]) = \sigma^{-2} \left[ D_{\text{LOS}} \mathbf{H}_{\text{LOS}}[k] \mathbf{H}_{\text{LOS}}^{H}[k] D_{\text{LOS}}^{H} - D_{\text{LOS}} \mathbf{H}_{\text{LOS}}[k] G_{\text{LOS}} \mathbf{H}_{\text{LOS}}^{H} - D_{\text{LOS}} \mathbf{H}_{\text{LOS}}[k] G_{\text{LOS}}^{H} \right]. \]  

\[ \rho_{\text{LOS}}^{(r,t)} = \frac{d_{Y}(t-1)}{\lambda_{n}} \cos \left( \frac{\alpha_{\text{LOS}}(t-1)^{\top}}{\| \mathbf{x} - \mathbf{u}_{j} \|^{2}} - \theta \right) - \frac{\| \mathbf{x} - \mathbf{u}_{j} \|^{2}}{\| \mathbf{x} - \mathbf{u}_{j} \|^{2}}. \]  

\[ \mathbf{g}_{\text{NLOS}} = J^{(l)}_{\mathbf{h}}(\mathbf{h}_{\text{true}}[k]) = \left[ \mathbf{\nabla}_{\mathbf{h}}(\mathbf{G}_{\text{LOS}}(\mathbf{a}_{\text{true}}) \mathbf{h}_{\text{LOS}}[k]) \right]^{\top} \mathbf{E} \left[ \mathbf{h}_{\text{LOS}}[k] - \mathbf{h}_{\text{true}}[k] \right]^{\top} \mathbf{E} \left[ \mathbf{h}_{\text{LOS}}[k] - \mathbf{h}_{\text{true}}[k] \right]^{\top} \mathbf{h}_{\text{true}}[k]^{\top} \mathbf{G}_{\text{LOS}}(\mathbf{a}_{\text{true}}). \]  

\[ \mathbf{B}_{\mathbf{h}}(\mathbf{x}[k]) = \sigma^{2} \left[ \mathbf{D}_{\text{LOS}} \mathbf{H}_{\text{LOS}}[k] \mathbf{H}_{\text{LOS}}^{H}[k] \mathbf{D}_{\text{LOS}}^{H} - \mathbf{D}_{\text{LOS}} \mathbf{H}_{\text{LOS}}[k] \mathbf{W}^{H} \left( \mathbf{W}^{H} \right)^{-1} \mathbf{W} \mathbf{H}_{\text{LOS}}^{H} \right], \]  

with \( \mathbf{D}_{\text{LOS}} \mathbf{H}_{\text{LOS}}[k] \mathbf{H}_{\text{LOS}}^{H}[k] \mathbf{D}_{\text{LOS}}^{H} \).
