What is already known on this topic

Neonatal administration of vitamin K by the intramuscular route is effective in the prevention of haemorrhagic disease in newborn babies but has been suggested as a possible risk factor for leukaemia in children.

A written record confirming that vitamin K has (or has not) been given is often not found, and some research groups have attempted to impute a child’s vitamin K status from hospital policy.

Nothing is known about how midwives interpret and implement vitamin K policies.

What this study adds

Earlier hospital policies were open to individual interpretation and they were not always followed.

There is considerable variation in current vitamin K policies and midwifery practice in the United Kingdom and no clear consensus on which babies should receive vitamin K intramuscularly.

We thank the midwives for enthusiastically sharing their knowledge and experience and Peter Hope and Pat Townsend for comments on an earlier draft of the paper.

Contributors: PA initiated the study, was involved in all its aspects, and is the guarantor; ER contributed to study design, interpretation of data, and writing of the paper; NTF and MJR contributed to many discussions on vitamin K and to writing the paper.

Funding: Data collection was funded by a nursing research fellowship awarded to PA by the Smith and Nephew Foundation. Other aspects of the study were funded by the Leukaemia Research Fund.

Relation between socioeconomic deprivation and death from a first myocardial infarction in Scotland: population based analysis

Kate Macintyre, Simon Stewart, James Chalmers, Jill Pell, Alan Finlayson, James Boyd, Adam Redpath, John McMurray, Simon Capewell

Health policy now explicitly addresses the increasing inequalities arising within many countries. Although it is generally accepted that socioeconomic factors influence the overall rates of coronary heart disease events, studies of case fatality after admission to hospital for acute myocardial infarction show only modest socioeconomic gradients. By focusing on those who survive to reach hospital, however, such studies may underestimate the true influence of socioeconomic deprivation. Reports suggest that around 70-80% of deaths within 30 days of a myocardial infarction occur before admission to hospital, and this proportion increases with age. We therefore examined the effect of socioeconomic deprivation not only on case fatality in patients admitted with myocardial infarction but also on the risk of death before admission.

Participants, methods, and results

Data were obtained from the Scottish Morbidity Record and General Register Office on all Scottish residents for whom a first myocardial infarction (code 410, international classification of diseases, 9th revision) was the principal cause of death or admission to hospital between 1986 and 1995. This database is linked to the Registrar General’s data on death certificates, with an accuracy of 98%. In a 1% sample of records checked in 1994, acute myocardial infarction as a principal diagnosis was 97% accurate. First myocardial infarction was defined as no previous admission for this event since 1981. Postcodes were used to assign a Carstairs deprivation category to each individual, from 1 (least deprived) to 5 (most deprived). These categories are derived from 1991...
census data on four variables: overcrowding, the proportion of residents unemployed, those who do not have a car, and those who belong to a low occupational social class. Population rates were calculated by using the population structure by age, sex, and deprivation category.

Between 1986 and 1995 in Scotland, 44 465 men (mean age (SD 11) 71.1) and 38 710 women (mean age (SD 10) 77.7) died before being admitted to hospital after a first myocardial infarction. A further 68 626 men and 49 123 women were admitted to hospital, of whom 22.3% (95% confidence interval 22.1% to 22.6%) died within 30 days. There was a socioeconomic gradient in all three parameters, which was greater in younger age groups (figure). The population based mortality in deprivation category 5 was more than twice that of category 1 in people aged under 65 (see table on website). Overall there were about 2000 excess deaths in the least affluent category compared with the most affluent (comparing the differential in observed over expected deaths in each deprivation category).

Comment

Socioeconomic deprivation has a profound effect on the risk of having a first myocardial infarction, the chance of reaching hospital alive, and the probability of surviving the first month. The effect of socioeconomic deprivation is greatest in women, with a twofold increase in death before reaching hospital in those under 65. The most deprived members of society under 65 have twice the risk of a first myocardial infarction. Anyone who experiences a first myocardial infarction do not survive to reach hospital, the potential of acute treatment to reduce mortality is limited. Reducing mortality from heart disease requires a focus on primary prevention that explicitly addresses socioeconomic inequalities.

Contributors: KM designed the study, performed the analyses and interpretation, and wrote the first and final draft of the paper. SS, JMcM, SC, JP, and JC contributed to the design and interpretation, and assisted with drafting the paper. AR, JB, and AR extracted the data and contributed to the interpretation and drafting of the paper. KM, JMcM, and SC will act as guarantors for the paper.

Funding: British Heart Foundation.

Email submissions from outside the United Kingdom

We offer an email submission service for authors from outside the UK. The address is papers@bmj.com

Ideally our email server would link seamlessly with our manuscript tracking system, but for now it does not, which is why we are offering the service only to authors outside the UK. Most post in the UK arrives the next day, so UK authors have the least to gain in speed of delivery from email delivery. As soon as our systems improve we will invite email submissions from everyone.

If you choose to send your submission by email please would you send the text and any tables and figures as attached files, together with a covering letter giving all your contact details (postal address, phone, fax, and email address). We can read files created with most word processing, graphics, and spreadsheet programs.

When your submission is received in our email box you will receive an automatic acknowledgment to show that it has arrived. If the submission is incomplete we will contact you and ask you to resend the missing information.

Once the submission is complete we will register it on our manuscript tracking system and you will receive a standard acknowledgment in the post.

Letters to the editor should continue to be sent direct to bmj.com as rapid responses or to letters@bmj.com
