Abstract

An experimental method has been used to estimate the dead space of planar Gunn diodes which were fabricated using GaAs and InP based materials, respectively. The experimental results indicate that the dead space was approximately 0.23 μm and the saturation domain velocity 0.96 × 10⁵ ms⁻¹ for an Al₀.₂₃Ga₀.₇₇As based device, while for an In₀.₅₃Ga₀.₄₇As based device, the dead space was approximately 0.21 μm and the saturation domain velocity 1.93 × 10⁵ ms⁻¹. Further, the results suggest that the saturation domain velocity is reduced or there is an increase in the dead-space due to local field distortions when the active channel length of the planar Gunn diode is less than 1 micron.

Keywords: dead space, planar Gunn diode, GaAs material, InP material

1. Introduction

There is a growing demand for a solid state terahertz source [1, 2] to occupy the small chip area, provide high RF power generation, and at a low operating dc voltage at room temperature. Recently in 2007, Khalid et al [3, 4] proposed and fabricated the first Al₀.₂₃Ga₀.₇₇As based planar Gunn diode operating above 100 GHz. The operating frequency of the planar Gunn diode is determined by the separation between the anode and cathode electrodes, which is known as the active channel length Lₜₐₖ. The active channel length and the saturation velocity vₛ determine the transit mode oscillation frequency (vₛ/Lₜₐₖ) of the Gunn diode. The first Al₀.₂₃Ga₀.₇₇As based planar Gunn diodes provided low RF output power of −43.5 dBm [3] at a fundamental frequency of 108 GHz. In 2011 Li et al [5] demonstrated a planar Gunn diode with seven parallel active channels providing an RF output power of −6.82 dBm at a fundamental operating frequency of 101 GHz.

In recent years planar Gunn diode technology has improved enabling operation in the higher milli-metric and low terahertz regions of the electromagnetic spectrum. Al₀.₂₃Ga₀.₇₇As based planar Gunn diodes with an anode to cathode separation of 1 μm have shown the highest fundamental operational frequency of 121 GHz recorded for a Al₀.₂₃Ga₀.₇₇As based Gunn diode; the RF output power was −9.3 dBm [6]. Very recently Khalid et al [7] published results for a In₀.₅₃Ga₀.₄₇As based Gunn diode fabricated on lattice matched InP substrate showing an operational fundamental frequency of 298 GHz with an RF output power of −25 dBm. The anode to cathode separation was 0.6 μm and represented the first sub-micron planar Gunn diode. Theoretically the transit fundamental oscillation frequency of the device can be increased by reducing the active channel length Lₜₐₖ. However, Monte Carlo simulations of the planar Gunn diode suggest Gunn oscillations cannot be maintained for active channel lengths which are approximately 0.6 μm [8, 9]. The Monte Carlo simulation also indicates the presence of a dead space
$L_{\text{dead}}$ (the distance it takes the Gunn domain to form in the active region). The simulation indicated the dead space was $\approx 0.25 \mu m$ for both GaAs and InP based planar Gunn diodes \cite{5, 9–11}. A similar dead space has been seen theoretically and experimentally in vertical Gunn diodes \cite{12–14}. The presence of the dead space will affect the transit mode frequency of operation and the efficiency of the planar Gunn diode as it reduces the active channel length and increases the parasitic channel resistance, respectively.

In this paper, both GaAs and InP material based planar Gunn diodes were fabricated with different active channel lengths in order to experimentally determine the active channel dead space. The device fundamental transit frequency was determined using a high frequency network analyzer and for the lower frequencies, the measurement was substantiated using spectrum analyzer measurements. Using the experimental fundamental frequency and knowing the physical active length the dead space was determined. The results indicate that the dead space associated with Al$_{0.23}$Ga$_{0.77}$As ($\approx 0.23 \mu m$) and In$_{0.53}$Ga$_{0.47}$As ($\approx 0.21 \mu m$) based planar Gunn diodes was similar and constant as predicted by the Monte Carlo simulations, provided the active channel length was greater than 1 $\mu m$.

2. Fabrication of planar Gunn diodes on GaAs and InP based materials

2.1. Fabrication of device by using the GaAs material

The planar Gunn diode was developed by the Universities of Glasgow and Aberdeen, and figure 1 shows a schematic of the cross section of the material layers making up the device. The device material layers were grown by molecular beam epitaxy (MBE) and consisted of a highly doped GaAs layer (15 nm), 50 nm of undoped GaAs between 20 nm layers of double-$\delta$ doped Al$_{0.23}$Ga$_{0.77}$As forming the Gunn channel. These are grown on a 500 nm GaAs buffer layer grown directly on a 620 $\mu m$ thick semi-insulating GaAs substrate. The anode and cathode ohmic contact regions were defined by electron beam lithography (EBL) using polymethylmethacrylate (PMMA) resist and formed using Pd/Ge/Au/Pt/Au deposited by e-beam evaporation and annealed at 400 °C.

2.2. Fabrication of device by using the InP material

Figure 2 shows a schematic view of the physical cross-section of the planar Gunn diode. The same fabrication methodology was used to fabricate the In$_{0.53}$Ga$_{0.47}$As planar Gunn diode \cite{3, 7, 15, 16}. The device material layers were grown by MBE and consisted of a highly doped In$_{0.53}$Ga$_{0.47}$As layer ($8 \times 10^{16}$ cm$^{-3}$) with a 300 nm thick active channel layer, followed by 200 nm thick cap layer of In$_{0.53}$Ga$_{0.47}$As, with a doping density of $2 \times 10^{18}$ cm$^{-3}$. These layers were directly grown on a 600 $\mu m$ thick semi-insulating InP substrate. The $nL_{\text{ac}}$ product of both the GaAs and InP based planar Gunn diodes were designed to be greater than $10^{12}$ cm$^{-2}$, where $n$ is the free carrier density and $L_{\text{ac}}$ is the separation distance between the anode and cathode \cite{17}. The anode and cathode low resistance ohmic contact layer was again defined by EBL using a polymethylmethacrylate (PMMA) resist and formed using Pd/Ge/Au/Pt/Au deposited by e-beam evaporation and annealed at 400 °C.

3. Planar Gunn diode measurements

A selection of GaAs and InP based planar Gunn diodes with different active channel lengths were dc and RF characterized. The active channel length of these devices was between 4 and 1 $\mu m$ in steps of 1 $\mu m$. The pulsed IV characteristics were first measured using a probe station connected to an automatic pulsed IV plotting system (Agilent semiconductor device analyzer B1500). This enabled devices with a negative resistance region to be identified for RF characterization.

The calculated expected transit oscillation frequencies using equation (1) for the different active channel lengths for both the Al$_{0.23}$Ga$_{0.77}$As and In$_{0.53}$Ga$_{0.47}$As based planar Gunn diodes are given in table 1. The calculation was made assuming the domain velocity was $1 \times 10^{5}$ m sec$^{-1}$ for Al$_{0.23}$Ga$_{0.77}$As \cite{3, 6} and $2.25 \times 10^{5}$ m sec$^{-1}$ \cite{7} for In$_{0.53}$Ga$_{0.47}$As.

criterion that the transit frequency corresponded to the maximum magnitude of $S_{11}$. The $\text{Al}_{0.23}\text{Ga}_{0.77}\text{As}$ and $\text{In}_{0.53}\text{Ga}_{0.47}\text{As}$ device dc operating voltages for the S-parameter measurements are given in table 2. The channel length of these devices stepped from 1 to 4 $\mu$m in 1 $\mu$m steps.

To verify this criterion spectrum analyser results were used on devices operating at the lower transit oscillation frequencies, i.e. those devices where the active channel length was 4 $\mu$m. The single port S-parameters were measured using the VNA as frequencies approaching 220 GHz could be measured which corresponded to the shorter channel length of devices fabricated on $\text{In}_{0.53}\text{Ga}_{0.47}\text{As}$ material (see table 1).

The VNA S-parameter set-up consisted of calibrated 50 Ohm GSG probes attached to an Agilent network analyzer operating from 10 MHz to 110 GHz and 140 GHz to 220 GHz. Single port $S_{11}$ measurements were made on both a GaAs and InP based planar Gunn diodes with a 4 $\mu$m active channel length. The measurements indicate natural frequencies of operation of 28 and 62.8 GHz, respectively. These natural oscillation frequencies were verified using spectrum analyser measurements. The spectrum analyser measurement set-up consisted of Agilent E4448 spectrum analyser, CPW probe and W-band mixer. Figure 3 shows the spectrum analyzer measurements on GaAs and InP based devices with an active channel length of 4 $\mu$m. The 4 $\mu$m GaAs based planar Gunn diode oscillated (dc = 4.46 V) at 27.67 GHz with an RF output power of $-23.4$ dBm and the 4 $\mu$m InP device (dc = 3.76 V) oscillated at 63.5 GHz with an RF output power of $-6.64$ dBm. These frequencies were similar to those measured using the VNA and the criterion of maximum $S_{11}$.

It was found that the oscillation frequency of GaAs and InP device were higher than the figures calculated in table 1. To verify the physical separation between the anode and cathode electrodes a scanning electron microscope (SEM) was used. The electrode separation of the devices selected for RF measurement were measured and found to correspond to the designed active channel lengths. The increase in the measured transit frequency can be explained by the existence of a dead space in the active channel length, which effectively reduces the channel length as reported by Li et al [5, 15]. The dead space can be estimated by using equation (2) and by plotting the measured transit time ($1/(\text{transit frequency of oscillation})$) against active channel length $L_{ac}$.

$$L_{\text{dead}} = L_{ac} - \frac{v_{\text{domain}}}{f} \text{ (GHz)}$$

The experimentally estimated dead space for both the GaAs and InP based planar Gunn diodes are shown in figures 4 and 5, respectively. The results indicate for $\text{Al}_{0.23}\text{Ga}_{0.77}\text{As}$ based planar Gunn diodes the dead space was 0.23 $\mu$m and the saturation domain velocity was 0.96 x 10^5 m s^{-1}. This velocity is consistent with the estimated electric field of between 1 to 2 MV m^{-1} for the devices with channel widths of 2 to 4 microns. The dead space appeared to be almost constant between 1.5 to 4 $\mu$m active channel lengths. As 1 $\mu$m channel length was approached the plot started to show some non-linearity, which indicated a reduction in the saturation domain velocity, or an increase in the dead space. Similar trends were observed for the InP based planar Gunn diode. The experimental results also included the published transit mode frequency for a 0.6 $\mu$m [7] and a 0.7 $\mu$m [18] active channel length $\text{In}_{0.53}\text{Ga}_{0.47}\text{As}$ planar Gunn diodes. The estimated dead space was 0.21 $\mu$m for channel lengths of 4 $\mu$m approaching 1$\mu$m and the estimated saturation domain velocity was 1.93 x 10^5 m s^{-1}. This experimental work verifies that the saturation domain velocity for the $\text{In}_{0.53}\text{Ga}_{0.47}\text{As}$ planar Gunn diode was approximately twice saturation domain velocity of the $\text{Al}_{0.23}\text{Ga}_{0.77}\text{As}$ based planar Gunn diode [7]. Below 1 $\mu$m the plot starts to show non-linearity effects indicating a reduction in the saturation domain velocity or an increase in the dead space. The experimental measurements agreed well with Monte Carlo simulation of the planar Gunn diode by Dunn et al [9] who reported a constant dead space for planar Gunn diodes with active channel lengths greater than 1 $\mu$m.

### 4. Conclusion

The paper describes experimental measurements of the dead space for both $\text{Al}_{0.23}\text{Ga}_{0.77}\text{As}$ and $\text{In}_{0.53}\text{Ga}_{0.47}\text{As}$ based planar Gunn diodes on GaAs and InP substrates, respectively. The results verify that the saturation domain velocity for $\text{In}_{0.53}\text{Ga}_{0.47}\text{As}$ was approximately twice that for $\text{Al}_{0.23}\text{Ga}_{0.77}\text{As}$ based planar Gunn diodes. The results also indicated that the dead space for the GaAs based planar Gunn diode was 0.23 $\mu$m and 0.21 $\mu$m for InP based planar Gunn diode and both constant for the active channel lengths greater than 1 $\mu$m, as predicted by Monte Carlo simulations. The
experimental work also indicated that for active channel lengths of less than 1 $\mu$m non-linear effects were seen which could result in an increase in the dead-space, a reduction in the domain velocity or a combination of both effects.

Acknowledgment

The authors would like to thank the staff of the James Watt Nanofabrication Centre at the University of Glasgow for help in fabricating the devices which is reported in this paper. Part of this work was supported by ESPRC through EP/H011862/1, and EP/H012966/1.
