## Poly[methylamine- $\mu$-oxalato-copper(II)]

The six-coordinate copper(II) ions in the title compound, $\left[\mathrm{Cu}\left(\mathrm{C}_{2} \mathrm{O}_{4}\right)\left(\mathrm{CH}_{5} \mathrm{~N}\right)\right]$, experience a Jahn-Teller distortion. The structure is a two-dimensional coordination network, with three crystallographically independent oxalate ions, two of them centrosymmetric, bridging $\mathrm{Cu}^{\mathrm{II}}$ ions in three different coordination modes. Each Cu ion is also coordinated by methylamine which is involved in both intra- and interlayer hydrogen bonding.

## Comment

The oxalate ligand is known for its chelating and bridging coordination modes. It is used by magnetochemists to mediate significant exchange interactions and can result in magnetically ordered materials (Coronado et al., 2000; Decurtins et al., 1993; Demunno et al., 1995; Hursthouse et al., 2004; Julve et al., 1984; Keene et al., 2004; Mathoniere et al., 1996; Price et al., 2001). We present here the structure of $\left[\mathrm{Cu}(\mathrm{ox})\left(\mathrm{CH}_{3} \mathrm{NH}_{2}\right)\right]$ (ox = oxalate), (I).

(I)

The asymmetric unit of (I) contains two Cu atoms, two methylamine molecules, and one complete and two halves of oxalate anions (Fig. 1). The $\mathrm{Cu}^{\text {II }}$ cations each have a $\mathrm{CuNO}_{5}$ coordination and show a large Jahn-Teller-induced tetragonal elongation. While the coordination environment of each $\mathrm{Cu}^{\text {II }}$ ion is very similar (Table 1), the coordination of the three oxalate ions differs significantly (Fig. 2). The structure of (I) is a complex two-dimensional coordination network that can best be viewed by initially considering only the short $\mathrm{Cu}-\mathrm{O} / \mathrm{N}$ contacts $(<2.05 \AA)$. The structure is built from two distinct copper oxalate chains. Chain $A$ (Fig. 3) is formed from Cu 1 and the oxalate containing C 1 and C 2 ; it consists of a simple

Figure 1
Fig. 1. The asymmetric unit of (I) and selected symmetry-equivalent atoms, showing the coordination of both metal ions and ligands. Displacement ellipsoids are drawn at the $40 \%$ probability level and H atoms have been omitted for clarity. [Symmetry codes: (i) $1-x,-y,-z$; (ii) $1-x,-y, 1-z$; (iii) $x, \frac{1}{2}-y, \frac{1}{2}+z$; (iv) $\left.x, \frac{1}{2}-y,-\frac{1}{2}+z\right]$.

alternation of these components, with a $|-\mathrm{Cu} 1-\mathrm{ox} B|_{n}$ repeat unit and a $\mathrm{Cu} \cdots \mathrm{Cu}$ separation of 5.530 (3) $\AA$. Chain $B$ (Fig. 3) is built from Cu 2 and the crystallographically centrosymmetric oxalate anions containing C3 and C4. It has a more complex topology with a $|-\mathrm{Cu} 2-\mathrm{ox} A-\mathrm{Cu} 2-\mathrm{ox} C-|_{n}$ repeat unit and alternating $\mathrm{Cu} \cdots \mathrm{Cu}$ separations of 5.537 (9) and 5.192 (9) $\AA$. The longer $\mathrm{Cu}-\mathrm{O}$ interactions link neighbouring chains into a corrugated two-dimensional structure in the $b c$ plane (Fig. 4). The coordinated methylamine displays both intra- and interlayer hydrogen bonding (Table 2).

Surprisingly, there are very few structures that contain copper and either methyl- or ethylamine. Chemically, the most

similar compound with a known structure is $\left[\mathrm{Cu}\left(\mathrm{NH}_{3}\right)(\mathrm{ox})\right]$ (Cavalca et al., 1972). Indeed, the structure of this compound shows remarkable similarity to that of (I). $\left[\mathrm{Cu}\left(\mathrm{NH}_{3}\right)(\right.$ ox $\left.)\right]$ also has a two-dimensional character, being built from $\mathrm{Cu}(\mathrm{ox})$ chains with the type $B$ structure described above. Here, neighbouring chains are linked through the long $\mathrm{Cu}-\mathrm{O}$ interactions into a two-dimensional sheet structure, with a topology that is different from that seen in (I).

## Experimental

Single crystals of (I) were synthesized by dissolving synthetic mooloolite, viz. $[\mathrm{Cu}(\mathrm{ox})] \cdot 0.33 \mathrm{H}_{2} \mathrm{O}(1.000 \mathrm{~g}, 6.35 \mathrm{mmol})$, in an aqueous methylamine solution ( $20 \mathrm{ml}, 40 \% w / w$ ). The resultant darkblue solution was further diluted with distilled water to a volume of 100 ml and left to evaporate. Blue crystals of (I) formed as a minor product amongst a large proportion of finely divided $[\mathrm{Cu}(\mathrm{ox})] \cdot 0.33 \mathrm{H}_{2} \mathrm{O}$.
