

1 **SUPPORTING INFORMATION - APPENDIX 1**

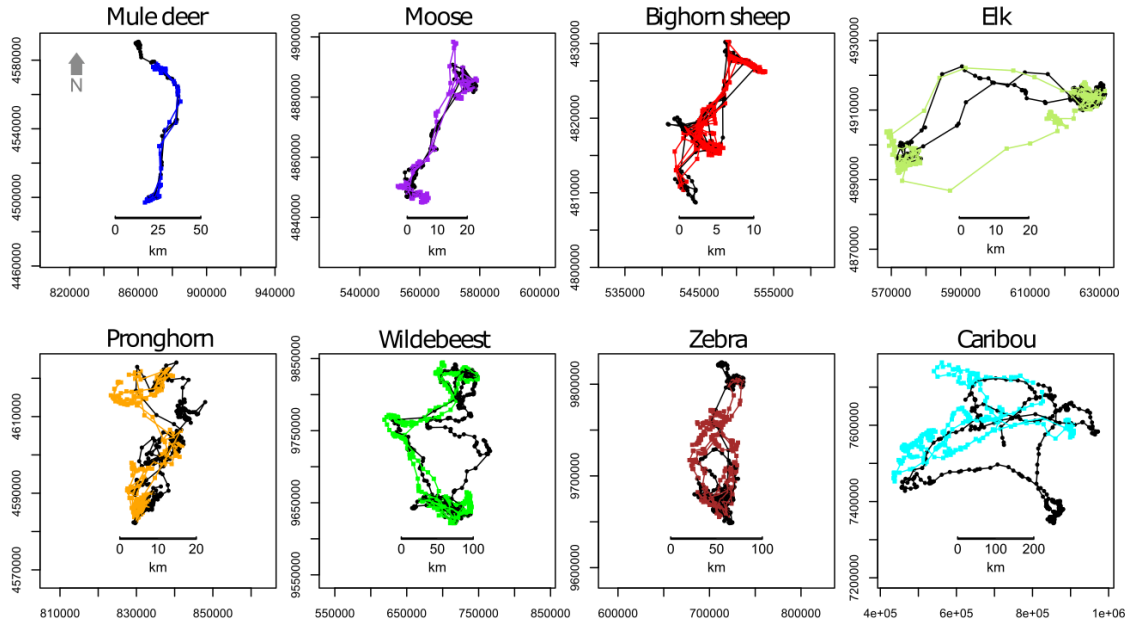

2 **Fig S1.** Map showing the home ranges (as minimum convex polygons) of all individuals in the

3

4

5 **Fig. S2.** Example trajectories illustrating variation in the strength of inter-year site fidelity across
6 two years. Data come from a representative individual mule deer, moose, bighorn sheep, elk,
7 pronghorn, wildebeest, zebra and caribou. Trajectories are shaded black in year 1 and coloured in
8 year 2.

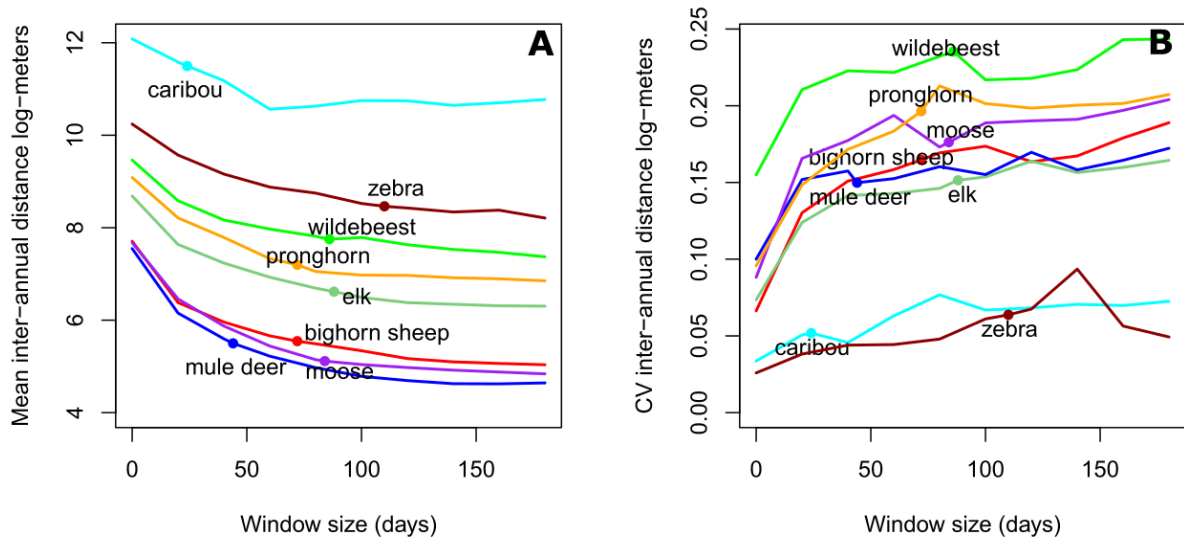

9

10

11 *Sensitivity of site fidelity metric to inter-annual variability*

12 Our analysis of site fidelity attempted to account for variation in the timing of movements
13 across years by calculating fidelity within a moving window of time. We examined the
14 sensitivity of our metric of site fidelity (inter-annual distance log-meters) to variation in the size
15 of the window across the eight ungulate species (Fig. S1). We varied the size of the window over
16 which the focal location in year_t was compared to the set of locations in year_{t-1}, and calculated
17 the mean inter-annual distance per individual, then the mean of all individuals across species.

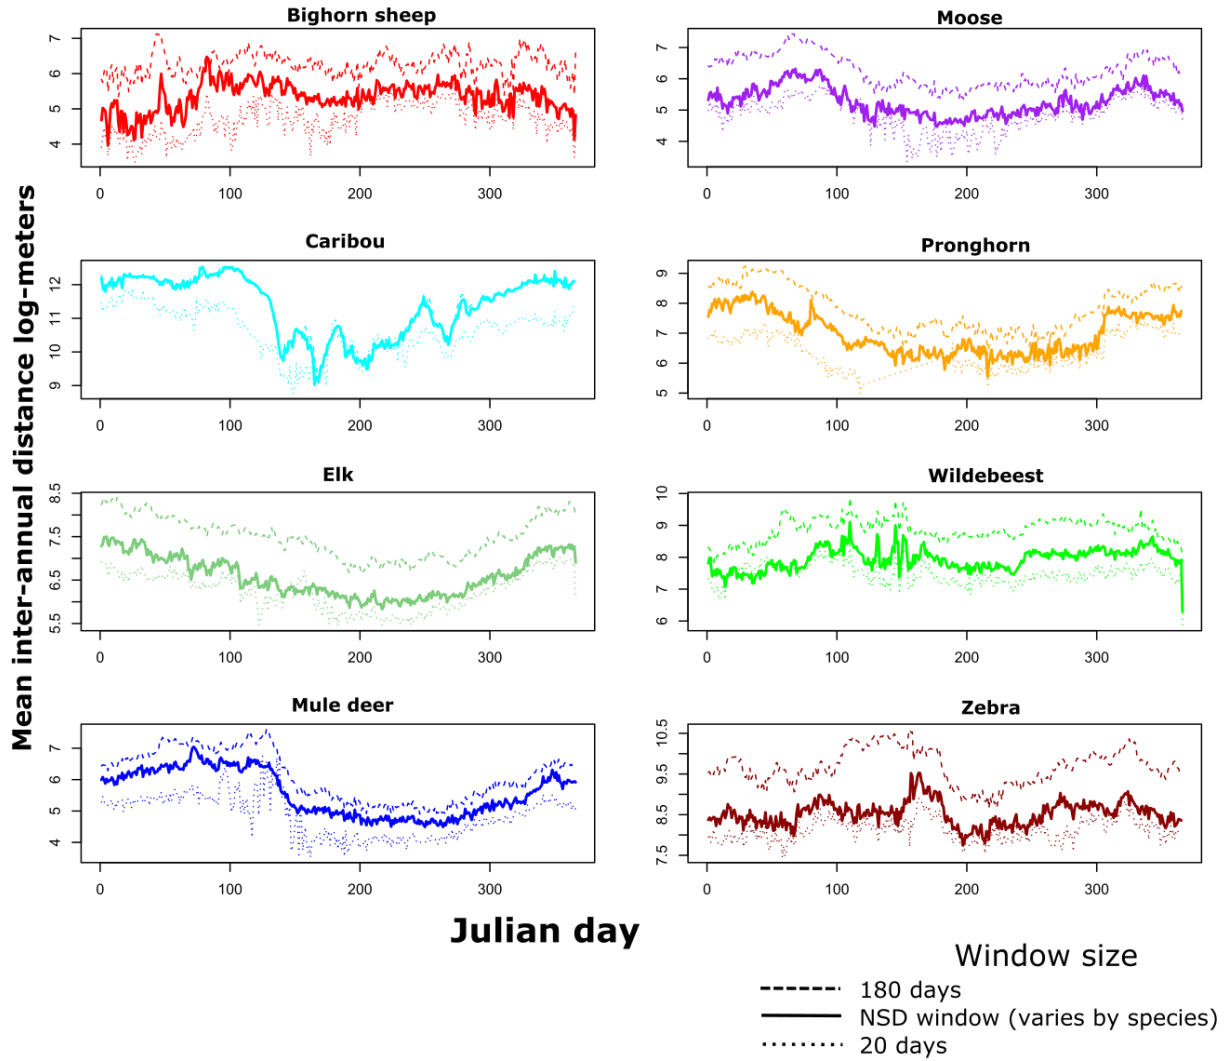

18 Our results show that inter-annual distances were relatively insensitive to changes in the
19 window size, particularly for window sizes larger than roughly >25-40 days. The proportional
20 change in inter-annual distance between the selected window and the maximum window (180
21 days) was relatively small: bighorn sheep (0.092), caribou (0.063), elk (0.047), mule deer
22 (0.156), moose (0.054), pronghorn (0.048), wildebeest (0.049) and zebra (0.030). Caribou inter-
23 annual distances increased slightly at larger window sizes because of sampling variance caused
24 by relatively small sample sizes (i.e. number of individuals) at large window sizes. The
25 coefficient of variation also saturated after roughly 25 days, except in bighorn sheep and elk.
26 Relative patterns of site fidelity across Julian dates were generally insensitive to variation in
27 window sizes (Fig S2).

28

29 **Fig. S3.** Sensitivity of the site fidelity metric (inter-annual distance log-meters) across a range of
 30 temporal window sizes. (A) mean inter-annual distances across individuals and (B) coefficient of
 31 variation of inter-annual distances across individuals. The large dots indicate the window sizes
 32 used in the study for each species, and reflect the mean variability (SD) in movement timing
 33 across consecutive years, as identified by fitting models of net squared displacement to
 34 movement data and estimating phenological parameters associated with saltatory movements
 35 (see Methods in main text; Table 1).

36

37

38 **Fig. S4.** Site fidelity (inter-annual distance log-meters) as a function of Julian date, across three
 39 window sizes: 180 days (dashed lines), 20 days (dotted line) and species-specific window sizes,
 40 identified by net-squared displacement.

41

42

43 *Sensitivity of model results to window size*

44 We re-ran the five linear mixed effects models to determine if main results of our study
45 (c.f. Table 2) were sensitive to window size decisions. We chose two window sizes (40 days and
46 120 days) and re-ran all models using a similar approach as the main study. We chose window
47 size of 40 days because the site fidelity metric (*IYD*) stabilized after 25-40 days, as noted above.
48 Window sizes larger than 120 days became data limiting, as larger window sizes required longer
49 GPS datasets for each individual.

50 Window size did not qualitatively change the main results of the study (Tables S1 & S2),
51 with the exception of Model 4 that tested whether site fidelity was related to *Days from peak*
52 *IRG*. Similar to the main study findings, the strongest driver of *IYD* across all window sizes was
53 *Temporal periodicity* which showed a strong negative effect on *IYD* with no significant
54 interactions with species. *Temporal constancy* also had no effect on *IYD* in either window size,
55 while *Spatial constancy* was negatively related to *IYD*. The effect of *Spatial constancy* interacted
56 with species in a similar way as the findings from the main text: elk, mule deer and moose were
57 predicted to increase with *Spatial constancy*. The effect of *Days from peak IRG* on *IYD* was not
58 detectable as an interaction with mule deer, suggesting this result is not as robust as those
59 involving predictability metrics. Finally, we found no effect of *Age* on *IYD* in any window size.

60

61 **Table S1.** Summary of coefficient estimates (β) and standard errors (SE) from general linear mixed-models of inter-year site fidelity for Window
62 size of 40 days applied to all species. Confidence intervals of β that did not overlap zero at the 0.05 (bold) levels.
63 *Model selection with AIC suggested *Age* model lacked an age effect.
