## Dalton Transactions

This is an Accepted Manuscript, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this Accepted Manuscript with the edited and formatted Advance Article as soon as it is available.

You can find more information about Accepted Manuscripts in the Information for Authors.

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal's standard Terms \& Conditions and the Ethical guidelines still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this Accepted Manuscript or any consequences arising from the use of any information it contains.

# From Tetranuclear to Pentanuclear [Co-Ln] (Ln = Gd, Tb, Dy, Ho) Complexes Across the Lanthanide Series: Effect of Varying Sequence of Ligand Addition

#### Abstract

Two new families of cobalt(II/III)-lanthanide(III) coordination aggregates have been reported: Tetranuclear $\left[\mathrm{Ln}^{\mathrm{III}}{ }_{2} \mathrm{Co}^{\mathrm{III}}{ }_{2} \mathrm{~L}_{2}(\mathrm{~N}-\mathrm{BuDEA})_{2}\left(\mathrm{O}_{2} \mathrm{CCMe}_{3}\right)_{4}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right] \cdot(\mathrm{MeOH})_{n} \cdot\left(\mathrm{H}_{2} \mathrm{O}\right)_{\mathrm{m}}(\mathrm{Ln}=\mathrm{Gd}, \mathbf{1} ; \mathrm{Tb}$, 2; Dy, 3; $\mathrm{n}=2, \mathrm{~m}=10$ for $\mathbf{1}$ and 2; $\mathrm{n}=6, \mathrm{~m}=2$ for 3) and Pentanuclear $\mathrm{Ln}^{\mathrm{III}}{ }_{2} \mathrm{Co}^{\mathrm{II}} \mathrm{Co}^{\mathrm{III}}{ }_{2} \mathrm{~L}_{2}(\mathrm{~N}-$ $\mathrm{BuDEA})_{2}\left(\mathrm{O}_{2} \mathrm{CCMe}_{3}\right)_{6}(\mathrm{MeOH})_{2}(\mathrm{Ln}=\mathrm{Dy}, \mathbf{4} ; \mathrm{Ho}, \mathbf{5})$ formed from the reaction of two aggregation assisting ligands $\mathrm{H}_{2} \mathrm{~L}$ ( $o$-vanillin oxime) and $\mathrm{N}-\mathrm{BuDEAH}_{2}$ ( $\mathrm{N}-$ butyldiethanolamine). A change in preference from lower to higher nuclearity structure was observed on going across the lanthanide series brought about by the variation in size of the $\operatorname{Ln}^{\text {III }}$ ions. An interesting observation was made for the varying sequence of addition of the ligands in the reaction medium paving the way to access both structural types for $\mathrm{Ln}=\mathrm{Dy}$. HRMS (+ve) of solutions gave further insight into the formation of the aggregates via different pathways. The tetranuclear complexes adopt a modified butterfly structure with a more complex bridging network while trapping of an extra $\mathrm{Co}^{\mathrm{II}}$ ion in the pentanuclear complexes destroy this arrangement putting the Co-Co-Co axis above the Ln-Ln axis. Direct current (dc) magnetic susceptibility measurements reveal weak antiferromagnetic coupling in 1. Complexes 2 and 5 display no slow magnetic relaxation, whereas complexes $\mathbf{3}$ and $\mathbf{4}$ display out-of-phase signals at low temperature. All

compounds were analyzed with DFT and CASSCF calculations and information about the single-ion anisotropies and mutual $4 f-4 f / 4 f-3 d$ magnetic interactions were derived.

## Introduction

The choice of ligand anions and solution phase reaction conditions are important parameters which can guide the synthesis of polynuclear aggregates although their formation is poorly understood and they are mostly synthesized serendipitously. ${ }^{1}$ Recent efforts to understand the complex pathways for the aggregation processes has shed some light in this area. ${ }^{2,3,4,5}$ During the past two decades, synthesis and characterization of multimetallic complexes based on $3 d$ and $4 f$ ions in single molecular entity have attracted great interest because of their potential singlemolecule magnet (SMM) behaviour. The construction of polynuclear aggregates of desired shape with precise control over the position and coordination environment of the different types of metal ion is a challenge on its own. A possible strategy employed in the synthesis of $3 d-4 f$ molecules is the use of hard-soft donors for discriminatory coordination of $3 d$ and $4 f$ ions. ${ }^{6}$ Though successful in certain aspects, this cannot help predict the structure of the final compound in polynuclear aggregate synthesis. Hence it is imperative to understand the mechanism of formation of coordination aggregates in order to advance the study of self-assembly. ${ }^{7}$ In recent years mass spectrometry has become a useful tool for investigation of formation of cluster molecules in solution. ${ }^{2,3,4,5,7,8}$

The formation and nuclearity of coordination aggregates also depends on the electronic configuration and ionic radius of the metal ions, which consequently determines its coordination number. ${ }^{9 \mathrm{a}}$ In the case of $4 f$ metal ions the change in ionic radius across the series is more pronounced due to lanthanide contraction. The effect of this phenomenon on $3 d-4 f$ cluster formation has not been explored in detail for $4 f$ metal ions. ${ }^{9 b, 9 c, 9 \mathrm{~d}}$ In a previous study we showed the effect of lanthanide ion size on the oxidation state of cobalt ions. ${ }^{5 b}$ The aim for the introduction of lanthanide ions in coordination clusters is to take advantage of their considerable single ion anisotropy and large spin ${ }^{10}$ while the presence of $3 d$ ions in close proximity to the $4 f$ ions brings in stronger exchange interactions ${ }^{11}$ compared to the weak $4 f-4 f$ dipolar interaction. ${ }^{12}$ The $3 d^{7}$ octahedral $\mathrm{Co}^{\text {II }}$ ion in high spin state is characterized by strong spin orbit coupling and its usefulness for slow magnetic relaxation is known. ${ }^{13}$ On the other hand the presence of diamagnetic low spin $\mathrm{Co}^{\mathrm{III}}$ in conjunction with paramagnetic $\mathrm{Ln}^{\mathrm{III}}$ also tends to affect the magnetization reversal energy barrier. ${ }^{14}$

Compared to the study of assembly of coordination cluster molecules using one "key" ligand, studies of systems with mixed ligands possess greater difficulties due to competition between ligands. ${ }^{15}$ In this respect use of ligands varying in denticity and coordination preferences is expected to simplify the issue. Phenol based oxime ligands are known to form homometallic as well as heterometallic polynuclear aggregates with or without the utilization of the bridging potency of the $=\mathrm{N}^{-} \mathrm{O}^{-}$group. ${ }^{16}$ Similarly polyalcohol amines tend to sequester multiple metal ions via their bridging alkoxido arms. ${ }^{17}$ Substituted diethanolamines have been utilized for the synthesis of $3 d-4 f$ complexes with the familiar butterfly topology having the $4 f$ ion in the body position. ${ }^{18}$ Previously both these two types of ligands were used together for the synthesis of $\mathrm{Mn}_{3} \mathrm{Ln}_{4}$ clusters ${ }^{19}$ but their formation was not investigated in detail nor could other structural types be accessed.

In this work we have utilized $o$-vanillin oxime $\left(\mathrm{H}_{2} \mathrm{~L}\right)$ in conjunction with N -Butyldiethanolamine $\left(\mathrm{N}-\mathrm{BuDEAH}_{2}\right) \quad(\mathrm{Chart} 1)$ to explore their reactivity towards $\mathrm{Co}_{2}(\mu$ $\left.\mathrm{OH}_{2}\right)\left(\mathrm{O}_{2} \mathrm{CCMe}_{3}\right)_{4}\left(\mathrm{HO}_{2} \mathrm{CCMe}_{3}\right)_{4}$ for the formation of $\mathrm{Co}^{\mathrm{II} / \mathrm{II}}-\mathrm{Ln}^{\mathrm{III}}$ aggregates. Interestingly a transition was observed from a tetranuclear $\mathrm{Ln}^{\mathrm{II}}{ }_{2} \mathrm{Co}^{\mathrm{III}}{ }_{2}$ structure to a pentanuclear $\mathrm{Ln}^{\mathrm{III}}{ }_{2} \mathrm{Co}^{\mathrm{II}} \mathrm{Co}^{\mathrm{III}}{ }_{2}$ structure on going across the lanthanide series $(\mathrm{Ln}=\mathrm{Gd}, \mathrm{Tb}, \mathrm{Dy}, \mathrm{Ho})$. Interestingly, variation in the sequence of ligand addition gave access to both the structural types. HRMS analysis of solutions revealed the various pathways for formation of the aggregates made possible by the differential cleavage of the dinuclear structure of $\operatorname{Co}_{2}(\mu$ $\left.\mathrm{OH}_{2}\right)\left(\mathrm{O}_{2} \mathrm{CCMe}_{3}\right)_{4}\left(\mathrm{HO}_{2} \mathrm{CCMe}_{3}\right)_{4}$ by the two ligands. The various binding modes of the pivalate ion observed in this work are represented in Chart S1.

Chart 1. Metal ion coordination and bridging potential of $\mathrm{L}^{2-}$ and $\mathrm{N}-\mathrm{BuDEA}^{2-}$ observed in this work.

## Experimental Section

Reagents and starting materials. Chemicals used were obtained from the following sources: Cobalt carbonate, hydroxylamine hydrochloride and sodium acetate from SRL India; triethylamine from Merck, India; pivalic acid from Sigma Aldrich; $\mathrm{Gd}\left(\mathrm{NO}_{3}\right)_{3} \cdot 6 \mathrm{H}_{2} \mathrm{O}$, $\mathrm{Tb}\left(\mathrm{NO}_{3}\right)_{3} \cdot 5 \mathrm{H}_{2} \mathrm{O}, \mathrm{Dy}\left(\mathrm{NO}_{3}\right)_{3} \cdot 5 \mathrm{H}_{2} \mathrm{O}, \mathrm{Ho}\left(\mathrm{NO}_{3}\right)_{3} \cdot 5 \mathrm{H}_{2} \mathrm{O}$ and N -Butyldiethanolamine from Alfa Aesar; o-vanillin from Spetrochem, India. All other chemicals and solvents used in this work were reagent-grade materials and were used as received without further purification.
$\mathrm{Co}_{2}\left(\mu-\mathrm{OH}_{2}\right)\left(\mathrm{O}_{2} \mathrm{CCMe}_{3}\right)_{4}\left(\mathrm{HO}_{2} \mathrm{CCMe}_{3}\right)_{4}$ was prepared according to a literature procedure. ${ }^{20}$ Cobalt carbonate ( $4.0 \mathrm{~g}, 34 \mathrm{mmol}$ ) was treated with an excess of pivalic acid ( $20.0 \mathrm{~g}, 196 \mathrm{mmol}$ ) in water $(3 \mathrm{~mL})$ at $100^{\circ} \mathrm{C}$ for 24 h , leading to dissolution of the carbonate salt. The solution was cooled to room temperature. $\mathrm{MeCN}(50 \mathrm{~mL})$ was added and the mixture was briefly stirred. The solution was then filtered and cooled to $5^{\circ} \mathrm{C}$, yielding pink crystals within one day. The crystals were collected and the solution was then cooled to $-4^{\circ} \mathrm{C}$ for 2 days to give a second crop. The second crop was collected by filtration, washed with cold MeCN and dried in air. Yield $=65.8$ $\%$.
$o$-vanillin oxime was synthesized according to reported literature procedure. ${ }^{16 \mathrm{f}}$

## Synthesis of Complexes

$\left[\mathrm{Ln}^{\mathrm{III}}{ }_{2} \mathrm{Co}^{\mathrm{III}}{ }_{2} \mathrm{~L}_{2}(\mathrm{~N}-\mathrm{BuDEA})_{2}\left(\mathrm{O}_{2} \mathrm{CCMe}_{3}\right)_{4}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right] \cdot(\mathrm{MeOH})_{\mathrm{n}} \cdot\left(\mathrm{H}_{2} \mathrm{O}\right)_{\mathrm{m}}(\mathrm{Ln}=\mathrm{Gd}, 1 ; \mathbf{T b}, 2 ; \mathrm{Dy}, 3 ;$ $\mathbf{n}=\mathbf{2}, \mathbf{m}=\mathbf{1 0}$ for $\mathbf{1}$ and $\mathbf{2}$; $\mathbf{n}=\mathbf{6}, \mathbf{m}=\mathbf{2}$ for 3). All three tetranuclear complexes (1-3) were obtained by following a general synthetic protocol. A 5 ml solution of $\mathrm{Co}_{2}(\mu-$ $\left.\mathrm{OH}_{2}\right)\left(\mathrm{O}_{2} \mathrm{CCMe}_{3}\right)_{4}\left(\mathrm{HO}_{2} \mathrm{CCMe}_{3}\right)_{4}(0.05 \mathrm{mmol})$ and $\mathrm{Ln}\left(\mathrm{NO}_{3}\right)_{3} \cdot \mathrm{xH}_{2} \mathrm{O}(0.1 \mathrm{mmol})$ in $\mathrm{MeOH} / \mathrm{DCM}$ (2:1) was treated with N -Butyldiethanolamine $\left(\mathrm{N}-\mathrm{BuDEAH}_{2}\right)(0.1 \mathrm{mmol})$ and stirred for 5 mins. $\mathrm{H}_{2} \mathrm{~L}(0.1 \mathrm{mmol})$ was added to the stirring solution followed by $\mathrm{Et}_{3} \mathrm{~N}(0.4 \mathrm{mmol})$ after another 5 mins. The resulting reddish brown solution was stirred for 3 h and filtered. The filtrate was left for slow evaporation of solvent and brown block shaped crystals suitable for single crystal X-ray analysis were formed over a period of 7 days. When $\mathrm{H}_{2} \mathrm{~L}$ is added before $\mathrm{N}-\mathrm{BuDEAH}$ the same tetranuclear complexes were isolated for $L n=G d, T b$ but for $L n=D y$ it gave rise to $\mathbf{4}$ the synthesis of which is discussed in the following section. Details about the reactions and individual complexes are delineated below.
$\left[\mathbf{G d}^{\text {III }}{ }_{2} \mathbf{C o}^{\mathbf{I I I}}{ }_{2}\right] \quad$ (1). $\quad \mathrm{Co}_{2}\left(\mu-\mathrm{OH}_{2}\right)\left(\mathrm{O}_{2} \mathrm{CCMe}_{3}\right)_{4}\left(\mathrm{HO}_{2} \mathrm{CCMe}_{3}\right)_{4} \quad\left(\begin{array}{lllll}0.0474 & \mathrm{~g}, & 0.05 & \mathrm{mmol}),\end{array}\right.$ $\mathrm{Gd}\left(\mathrm{NO}_{3}\right)_{3} \cdot 6 \mathrm{H}_{2} \mathrm{O}(0.0451 \mathrm{~g}, 0.1 \mathrm{mmol}), \mathrm{N}-\mathrm{BuDEAH}_{2}(16.6 \mu \mathrm{~L}, 0.1 \mathrm{mmol}), \mathrm{H}_{2} \mathrm{~L}(0.0167 \mathrm{~g}, 0.1$
$\mathrm{mmol})$ and $\mathrm{Et}_{3} \mathrm{~N}(55.6 \mu \mathrm{~L}, 0.4 \mathrm{mmol})$. Yield: $0.035 \mathrm{~g}(40 \%$ based on Gd$)$. Yield: $0.046 \mathrm{~g}(51 \%$ based on Ho$) ; 0.009 \mathrm{~g}(10 \%$ based on Ho when $\mathrm{N}-\mathrm{BuDEAH}_{2}$ is added before $\mathrm{H}_{2} \mathrm{~L}$ ). Anal.Calcd (\%) for $\mathrm{C}_{64} \mathrm{H}_{110} \mathrm{Co}_{3} \mathrm{Ho}_{2} \mathrm{~N}_{4} \mathrm{O}_{24}$ : C , 42.09; H, 6.07; N, 3.07. Found (\%): C, 42.10; H, 6.10; N, 3.10. Selected IR peaks: (KBr, $\mathrm{cm}^{-1}$, $\mathrm{vs}=$ very strong, $\mathrm{br}=$ broad, $\mathrm{s}=$ strong, $\mathrm{m}=$ medium, $\mathrm{w}=$ weak $): 3324-3550\left(\mathrm{br}, \tilde{v}_{\mathrm{OH}}\right), 1577(\mathrm{~s}$, $\tilde{v}_{\mathrm{C}=\mathrm{N}}$ ), 1547 (s, asym. $\tilde{v}_{\text {COO }}$ ), 1415 (s, sym. ${ }^{{ }^{\text {COOO }}}$ ). UV-vis: $\left.\lambda_{\text {max }}, \mathrm{nm}\left(\varepsilon, \mathrm{L} \mathrm{mol}^{-1} \mathrm{~cm}^{-1}\right)\right](\mathrm{MeOH})$ $=686$ (115), 540 (158), 508 (125), 448 (624), 372 (1900), 298 (10200), 252 (36400), 220 (21800).

Physical Measurements. A PerkinElmer model 240C elemental analyzer was used to perform the elemental analyses ( $\mathrm{C}, \mathrm{H}$ and N ). Solution electronic absorption spectra was recorded on a Shimadzu UV 3100 UV/Vis/NIR spectrophotometer while a PerkinElmer RX1 spectrometer were used to record the FTIR spectra. The electrospray ionization (ESI) high resolution mass spectra were collected on a Bruker Daltonics micrOTOF mass spectrometer.

SQUID measurements. All magnetic measurements were carried out on powdered crystalline samples restrained in eicosane using a Quantum Design MPMS 3 SQUID magnetometer. Data were corrected for the diamagnetic contribution of the sample holder and eicosane by measurements, and for the diamagnetism of each compound.

Theoretical calculations. The theoretical calculation at DFT level of theory were performed with ORCA 4.2 software. ${ }^{21}$ The PBE0 hybrid functional ${ }^{22}$ was used together with relativistic basis sets: SARC2-DKH-QZVP for Gd, Tb, Dy, Ho atoms, SARC2-DKH-QZV for Lu atoms, DKH-def2-TZVP for Co and DKH-def2-SVP for all other atoms. ${ }^{23}$ The Douglas-Kroll-Hess Hamiltonian was used to treat relativistic effects ${ }^{24}$ together with Gaussian finite nucleus model ${ }^{25}$ and the increased radial integration accuracy for metal atoms was also set. The auxiliary basis set SARC/J ${ }^{26}$ and the chain-of-spheres (RIJCOSX) approximation to exact exchange was also used. ${ }^{27}$ Generally, the experimental X-ray structures of $\mathbf{1 - 3}$ were used for such calculations, in which hydrogen atoms positions were normalized in Mercury software. ${ }^{28}$ In case of 4-5, the truncated structures were used in which hydrogen atoms were optimized with PBE0 functional. The calculated spin densities were visualized with VESTA 3 program. ${ }^{29}$

The state average complete active space self-consistent field (SA-CASSCF) wave functions calculations were done with OpenMOLCAS $19.11^{30}$ for $\mathbf{2 - 5}$ in such way that only one paramagnetic metal ion was preserved, and all others were replaced by diamagnetic ions. The active space was defined by five $d$-orbitals/seven $f$-orbitals and respective number of electrons for cobalt or lanthanide ions. The RASSCF method was used in the CASSCF calculations with the following numbers of multiplets: 7 septets, 140 quintets, 113 triplets, and 123 singlets for $\mathrm{Tb}^{\text {III }}$, 21 sextets, 224 quartets, and 490 doublets for $\mathrm{Dy}^{\text {III }}$, 35 quintets, 210 triplets, and 196 singlets for $\mathrm{Ho}^{\text {III }}, 10$ quartets and 40 doublets for $\mathrm{Co}^{\text {III }}$. In case of $\mathrm{Tb}^{\text {III }}, \mathrm{Ho}^{\text {III }}$ and $\mathrm{Co}^{\text {II }}$, all multiplets were included in the spin-orbit RASSI-SO procedure, while the number of states for Dy ${ }^{\text {III }}$ was limited as follows: 21 sextets, 128 quartets, and 130 doublets. ANO-RCC-VQZP was used for paramagnetic lanthanides, ANO-RCC-VTZP was applied for $\mathrm{Co}^{\mathrm{II}}$ and also for all donor atoms (N/O) of the paramagnetic ions, and ANO-RCC-MB was used for the rest of atoms. ${ }^{31}$

Crystal Data Collection and Refinement. Single crystal X-ray diffraction data for $\mathbf{1 - 5}$ were collected on a Bruker SMART APEX-II CCD X-ray diffractometer furnished with a graphitemonochromated Mo $\mathrm{K} \alpha\left(\lambda=0.71073 \AA\right.$ ) radiation by the $\omega$ scan (width of $0.3^{\circ}$ frame $^{-1}$ ) method at 100 K with a scan rate of 4 s per frame. SAINT and XPREP software ${ }^{32}$ was used for Data processing and space group determination. Direct method of SHELXS $2014^{33}$ was used to solve the structure and then refined with full-matrix least squares using the SHELXL-(2014/7) ${ }^{34}$ program package included into WINGX system Version 2014.1. ${ }^{35}$ Data were corrected for

Lorentz and polarization effects; an empirical absorption correction was applied using the SADABS. ${ }^{36}$ The locations of the heaviest atoms ( Ln and Co ) were determined easily. The O, N and C atoms were subsequently determined from the difference Fourier maps. These atoms are refined anisotropically. In the absence of electron densities in the Fourier map the H atoms were incorporated at calculated positions and refined with fixed geometry and riding thermal parameters with respect to their carrier atoms. The crystals of $\mathbf{1}-\mathbf{3}$ are susceptible to loss of crystallinity upon exposure to X-ray at room temperature making low temperature measurements a necessity and the best possible data has been presented. In $\mathbf{1}$ the C 17 atom was highly disordered and refined isotropically. Residual electron densities were observed near (~ $0.84 \AA$ ) Tb 1 in $\mathbf{1}$ which could not be modeled as any chemically sensible species. It is due to the presence of absorption artifacts caused by imperfections in absorption correction employed by the instrument. Such artifacts are sometimes observed when very heavy and strongly diffracting elements like lanthanides and actinides are present. ${ }^{37}$ No unresolved twinning could be identified. Due to the presence of huge number of solvent molecules in close proximity to each other, some of H atoms could not be fixed unambiguously. Crystallographic diagrams were presented using DIAMOND software. ${ }^{38}$ A summary of the crystal data and relevant refinement parameters is summarized in Table 1. Crystallographic data (including structure factors) have been deposited with the Cambridge Crystallographic Data Centre as supplementary publications CCDC-2090138, 2090137, 2090139, 2090141, 2090140. These data can also be obtained free of cost at www.ccdc.cam.ac.uk/conts/retrieving.html (or from the Cambridge Crystallographic Data Centre).

## Results and Discussion

Synthetic Methodology. o-vanillin oxime $\left(\mathrm{H}_{2} \mathrm{~L}\right)$ was prepared according to a literature procedure by the reaction of $o$-vanillin and hydroxylamine hydrochloride in the presence of sodium acetate in aqueous medium. ${ }^{16 f}$ Coordination reactivity of $\mathrm{H}_{2} \mathrm{~L}$ together with N Butyldiethanolamine $\left(\mathrm{N}-\mathrm{BuDEAH}_{2}\right)$ with Cobalt and $4 f$ metal ions were explored using $\mathrm{Co}_{2}(\mu-$ $\left.\mathrm{OH}_{2}\right)\left(\mathrm{O}_{2} \mathrm{CCMe}_{3}\right)_{4}\left(\mathrm{HO}_{2} \mathrm{CCMe}_{3}\right)_{4}$ and $\mathrm{Ln}\left(\mathrm{NO}_{3}\right)_{3} \cdot \mathrm{xH}_{2} \mathrm{O}(\mathrm{Ln}=\mathrm{Gd}, \mathrm{Tb}, \mathrm{Dy}, \mathrm{Ho})$ in the presence of $\mathrm{Et}_{3} \mathrm{~N}$ under varying order of ligand addition as summarized in Schemes 1 and 2. Reaction of $\mathrm{Co}_{2}\left(\mu-\mathrm{OH}_{2}\right)\left(\mathrm{O}_{2} \mathrm{CCMe}_{3}\right)_{4}\left(\mathrm{HO}_{2} \mathrm{CCMe}_{3}\right)_{4}$ and $\mathrm{Ln}\left(\mathrm{NO}_{3}\right)_{3} \cdot \mathrm{xH}_{2} \mathrm{O}(\mathrm{Ln}=\mathrm{Gd}$, Tb, Dy) first with N $\mathrm{BuDEAH}_{2}$ followed by $\mathrm{H}_{2} \mathrm{~L}$ in the presence of $\mathrm{Et}_{3} \mathrm{~N}$ in a $0.5: 1: 1: 1: 4$ molar ratio in $\mathrm{MeOH} / \mathrm{DCM}$ under stirring condition resulted in deep brown solutions from which brown blocked shaped crystals of tetranuclear $\mathbf{1}-\mathbf{3}$ were obtained in $40 \%, 42 \%$ and $45 \%$ yields, respectively (Eq. (1) and Scheme 1). Interestingly when $\mathrm{Co}_{2}\left(\mu-\mathrm{OH}_{2}\right)\left(\mathrm{O}_{2} \mathrm{CCMe}_{3}\right)_{4}\left(\mathrm{HO}_{2} \mathrm{CCMe}_{3}\right)_{4}$ and $\operatorname{Ln}\left(\mathrm{NO}_{3}\right)_{3} \cdot \mathrm{xH}_{2} \mathrm{O}$ $(\mathrm{Ln}=\mathrm{Dy}, \mathrm{Ho})$ was initially reacted with $\mathrm{H}_{2} \mathrm{~L}$ followed by sequential addition of $\mathrm{N}-\mathrm{BuDEAH}_{2}$ and $\mathrm{Et}_{3} \mathrm{~N}$ (order of addition of $\mathrm{H}_{2} \mathrm{~L}$ and $\mathrm{N}-\mathrm{BuDEAH}_{2}$ reversed) in a 1:1:0.5:1:4 ratio in $\mathrm{MeOH} / \mathrm{DCM}$ under stirring condition, it resulted in deep brown solutions from which brown blocked shaped crystals of pentanuclear 4 and 5 were obtained in $50 \%$ and $51 \%$ yields, respectively (Eq. (2) and Scheme 2). Complex 5 can also be synthesized by addition of N $\mathrm{BuDEAH}_{2}$ before $\mathrm{H}_{2} \mathrm{~L}$ but in much lower yields of $10 \%$. When $\mathrm{Ln}=\mathrm{Gd}, \mathrm{Tb}$, adding $\mathrm{H}_{2} \mathrm{~L}$ before $\mathrm{N}-\mathrm{BuDEAH}_{2}$ also resulted in tetranuclear $\mathbf{1}$ and 2. Thus the preference of nuclearity of the
complexes changes from four to five on going across the lanthanide series with both the structural types being accessed when $\mathrm{Ln}=\mathrm{Dy}$ through different sequence of addition of ligands in the reaction mixture.

$$

Scheme 1. Schematic representation for the formation of the complexes when $\mathrm{N}-\mathrm{BuDEAH}_{2}$ is added before $\mathrm{H}_{2} \mathrm{~L}$.

Scheme 2. Schematic representation for the formation of the complexes when $\mathrm{H}_{2} \mathrm{~L}$ is added before N BuDEAH $_{2}$.

Single-crystal X-ray structure analysis revealed the formation of tetranuclear $\left\{\operatorname{Ln}^{\mathrm{III}}{ }_{2} \mathrm{Co}^{\mathrm{III}}{ }_{2}\right\}(\mathbf{1}-\mathbf{3})$ and pentanuclear $\left\{\operatorname{Ln}^{\mathrm{III}}{ }_{2} \mathrm{Co}^{\mathrm{II}} \mathrm{Co}^{\mathrm{III}}{ }_{2}\right\}(4-5)$ neutral cores indicating that the varying course of addition of reactants and type of $4 f$ ions do control the nature of aggregation process. Elemental analysis and initial physical characterizations (measured immediately after collection from crystallization mixture) were in good agreement with the molecular formula $\mathrm{C}_{54} \mathrm{H}_{116} \mathrm{Co}_{2} \mathrm{Gd}_{2} \mathrm{~N}_{4} \mathrm{O}_{32}, \mathrm{C}_{54} \mathrm{H}_{116} \mathrm{Co}_{2} \mathrm{~Tb}_{2} \mathrm{~N}_{4} \mathrm{O}_{32}$ and $\mathrm{C}_{54} \mathrm{H}_{116} \mathrm{Co}_{2} \mathrm{Dy}_{2} \mathrm{~N}_{4} \mathrm{O}_{32}$ for 1-3, respectively and $\mathrm{C}_{64} \mathrm{H}_{110} \mathrm{Co}_{3} \mathrm{Dy}_{2} \mathrm{~N}_{4} \mathrm{O}_{24}$ and $\mathrm{C}_{64} \mathrm{H}_{110} \mathrm{Co}_{3} \mathrm{Dy}_{2} \mathrm{~N}_{4} \mathrm{O}_{24}$ for 4 and 5. In $\mathbf{1}-\mathbf{5}$, coordination of $\mathrm{Co}^{\text {II }}$ ions, derived from $\mathrm{Co}_{2}\left(\mu-\mathrm{OH}_{2}\right)\left(\mathrm{O}_{2} \mathrm{CCMe}_{3}\right)_{4}\left(\mathrm{HO}_{2} \mathrm{CCMe}_{3}\right)_{4}$, to $\mathrm{L}^{2-}$ and $\mathrm{N}-\mathrm{BuDEA}^{2-}$ under aerobic condition lead to their oxidation to $\mathrm{Co}^{\text {III }}$. The phenoxido O and N from $=\mathrm{N}-\mathrm{O}^{-}$group in $\mathrm{L}^{2-}$ lend a bidentate coordination site for $\mathrm{Co}^{\text {III }}$ ions while the O end of $=\mathrm{N}-\mathrm{O}^{-}$, bridges two $\mathrm{Ln}^{\text {III }}$ ions in $\mu_{2}$ fashion. The amine N of $\mathrm{N}-\mathrm{BuDEA}^{2-}$ coordinates to the $\mathrm{Co}^{\text {III }}$ center trans to the N from $=\mathrm{N}-\mathrm{O}^{-}$. In $\mathbf{1} \mathbf{- 3}$, one of the alkoxido arms of $\mathrm{N}-\mathrm{BuDEA}^{2-}$, bridges two $\mathrm{Ln}^{\mathrm{III}}$ ions and a $\mathrm{Co}^{\mathrm{III}}$ ion in $\mu_{3}$ mode whereas the other connects one $\mathrm{Ln}^{\text {III }}$ and one $\mathrm{Co}^{\text {III }}$ ions in $\mu_{2}$-bridging fashion. Unlike $1-\mathbf{3}$, in 4 and 5 the $\mu_{3}$ bridging alkoxido arm connects one $\mathrm{Ln}^{\text {IIII }}$, one $\mathrm{Co}^{\text {III }}$ and a $\mathrm{Co}^{\text {II }}$ ion while the O end of $=\mathrm{N}-\mathrm{O}^{-}$bridges two $\mathrm{Ln}^{\mathrm{III}}$ and one $\mathrm{Co}^{\mathrm{II}}$ in $\mu_{3}$ fashion trapping an additional $\mathrm{Co}^{\mathrm{II}}$ ion.

The tetranuclear cores of $\mathbf{1 - 3}$ can be described as having a butterfly like topology with folded wings with the $\mathrm{Ln}^{\mathrm{III}}$ ions in the central body position and $\mathrm{Co}^{\mathrm{III}}$ ions occupying the outer wing
positions. Unlike previously reported $\mathrm{Co}^{\mathrm{III}}-4 f$ butterfly structures the disposition of the metal ions and coordinating atoms within the core cannot be classified as partial dicubane or other known regular geometries (Chart 2, folding of wing tips shown by cyan circles) with the bridging network being more complex. Trapping of the additional $\mathrm{Co}^{\text {II }}$ ion in $\mathbf{4}$ and 5 destroys the butterfly like structure with two $\mathrm{Co}^{\mathrm{III}}$ and one $\mathrm{Co}^{\mathrm{II}}$ ions showing a nearly collinear arrangement having the $\mathrm{Co}-\mathrm{Co}-\mathrm{Co}$ axis placed above the $\mathrm{Ln}-\mathrm{Ln}$ axis in a non-parallel manner (Figure 5).

Chart 2. (a) Core of the butterfly like structure observed in present work and (b) partial dicubane core of previously reported butterfly structures. Folding of the wing tips in (a) compared to (b) are shown by cyan circles.

## Description of crystal structures

$\left[\mathrm{Ln}^{\mathrm{III}}{ }_{2} \mathrm{Co}^{\mathrm{III}}{ }_{2} \mathrm{~L}_{2}(\mathrm{~N}-\mathrm{BuDEA})_{2}\left(\mathrm{O}_{2} \mathrm{CCMe}_{3}\right)_{4}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right] \cdot(\mathrm{MeOH})_{n} \cdot\left(\mathrm{H}_{2} \mathrm{O}\right)_{m}(\mathrm{Ln}=\mathrm{Gd}, 1 ; \mathrm{Tb}, 2 ; \mathrm{Dy}$, 3; $\boldsymbol{n}=\mathbf{2 ,} \boldsymbol{m = 1 0}$ for 1 and 2; $\boldsymbol{n = 6 , m = 2}$ for 3). All the three complexes $\mathbf{1}-\mathbf{3}$ crystallizes in triclinic $P \overline{1}$ space group with $Z=1$. Selected metric parameters are listed in Table S1. The neutral tetranuclear complexes consist of a $\left\{\operatorname{Ln}^{\mathrm{III}}{ }_{2} \mathrm{Co}^{\mathrm{III}}{ }_{2}\right\}$ core having the general formula $\mathrm{Ln}^{\text {III }}{ }_{2} \mathrm{Co}^{\text {III }}{ }_{2} \mathrm{~L}_{2}(\mathrm{~N}-\mathrm{BuDEA})_{2}\left(\mathrm{O}_{2} \mathrm{CCMe}_{3}\right)_{4}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}$ formed with the help of two $\mathrm{L}^{2-}$ and two $\mathrm{N}-$ $\mathrm{BuDEA}^{2-}$ anions. The crystal lattices of $\mathbf{1}$ and $\mathbf{2}$ further accommodates ten water and two MeOH molecules while in $\mathbf{3}$ there are only two water and four MeOH molecules. The molecular structures of 1-3 are given in Figure 1. Since the complexes are isostructural, the structural description is given for the Gd derivative (1) as a representative case.

Figure 1. Molecular structures of 1-3. Hydrogen atoms and solvent molecules are omitted for clarity. Colour code: $\mathrm{Co}^{\text {III }}$ brown, $\mathrm{Gd}^{\text {III }}$ yellow, $\mathrm{Tb}^{\text {III }}$ blue-grey, $\mathrm{Dy}^{\text {III }}$ violet, N blue, O red, S orange, C grey.

Each $\mathrm{L}^{2-}$ anion provides a bidentate ON coordination site for a $3 d$ metal ion while a tridentate ONO coordination site is provided by the $\mathrm{N}-\mathrm{BuDEA}^{2-}$ anion. Coordination of both $\mathrm{L}^{2-}$ and $\mathrm{N}-$ $\mathrm{BuDEA}^{2-}$ to a $\mathrm{Co}^{\text {II }}$ center derived from $\mathrm{Co}_{2}\left(\mu-\mathrm{OH}_{2}\right)\left(\mathrm{O}_{2} \mathrm{CCMe}_{3}\right)_{4}\left(\mathrm{HO}_{2} \mathrm{CCMe}_{3}\right)_{4}$ leads to its aerial oxidation to $\mathrm{Co}^{\text {III }}$. Each $\mathrm{L}^{2-}$ anion coordinates to an octahedral $\mathrm{Co}^{\text {III }}$ ion in an equatorial manner while the $\mathrm{N}-\mathrm{BuDEA}^{2-}$ anion shows a facial mode of coordination. The O end of hydroxyl amine group of each $\mathrm{L}^{2-}$, in its deprotonated $=\mathrm{N}-\mathrm{O}^{-}$form, bridges two $\mathrm{Ln}{ }^{\text {III }}$ ions in a $\mu_{2}$ fashion. One of the alkoxido arms of the $\mathrm{N}-\mathrm{BuDEA}{ }^{2-}$ further connects two $\mathrm{Ln}^{\mathrm{III}}$ ions (in addition to $\mathrm{Co}^{\mathrm{III}}$ ) thus bridging the three metal centers in a $\mu_{3}$ fashion. The other arm extends a $\mu_{2}$-bridging mode towards an $\mathrm{Ln}^{\text {III }}$ ion connecting it to the $\mathrm{Co}^{\text {III }}$. Additional capping coordination by two $\mathrm{Me}_{3} \mathrm{CCO}_{2}{ }^{-}$anions, obtained from $\mathrm{Co}_{2}\left(\mu-\mathrm{OH}_{2}\right)\left(\mathrm{O}_{2} \mathrm{CCMe}_{3}\right)_{4}\left(\mathrm{HO}_{2} \mathrm{CCMe}_{3}\right)_{4}$, between a $\mathrm{Co}^{\mathrm{III}}$ and an $\mathrm{Ln}^{\text {III }}$ ion each in $\mu_{1,3}$ fashion lends further stability to the structure. Two more $\mathrm{Me}_{3} \mathrm{CCO}_{2}{ }^{-}$anions are consumed by the two $\mathrm{Ln}^{\mathrm{III}}$ ions for $\eta^{2}$ chelation. Presence of a water molecule on the $\mathrm{Ln}^{\text {III }}$ ions fulfills the distorted Muffin geometry around them.

Figure 2 shows the various intermetallic separations within the $\left\{\mathrm{Gd}_{2} \mathrm{O}_{2}\right\}$ core of $\mathbf{1}$. The O bridge from the $=\mathrm{N}-\mathrm{O}^{-}$group of $\mathrm{L}^{2-}$ showed Gd1-O3 distances at 2.429(3) and 2.438(3) $\AA$ while connecting the two $\mathrm{Gd}^{\mathrm{III}}$ centers asymmetrically (Figure S 2 ). The $\mu_{3}$ alkoxido arm of $\mathrm{N}-$ BuDEA $^{2-}$ demonstrated different Gd1-O4 and Co1-O4 distances of 2.539(3), 2.558(4) and 1.904 (3) $\AA$ respectively as did the $\mu_{2}$ alkoxido arm for $\mathrm{Gd} 1-\mathrm{O} 5$ and Co1-O5 at 2.407(4) and 1.907(3) $\AA$. Three different $\mathrm{M}-\mathrm{O}-\mathrm{M}$ angles were also recorded by the $\mu_{3}$ alkoxido arm at $116.45(15)^{\circ}, 97.05(13)^{\circ}$ and $84.75(10)^{\circ}$ corresponding to Co1-O4-Gd1 and Gd1-O4-Gd1. The bridge angle for the $\mu_{2}$ alkoxido arm stands at $101.52(14)^{\circ}(\mathrm{Co} 1-\mathrm{O} 5-\mathrm{Gd} 1)$ while that for the O end of $=\mathrm{N}-\mathrm{O}^{-}$is $89.80(11)^{\circ}(\mathrm{Gd} 1-\mathrm{O} 3-\mathrm{Gd} 1)$. The overall disposition of the four metal ion centers is more or less planar (Figure S3) with the bridging O atoms ( O 5 ) of $\mu_{2}$ alkoxido arms lying in the plane through Co 1 and Gd 1 while those $(\mathrm{O} 4)$ of the $\mu_{3}$ alkoxido arm are displaced by 1.025 $\AA$. The $\mu_{3} \mathrm{O}$ atom of $=\mathrm{N}-\mathrm{O}^{-}$sits $1.487 \AA$ away from this plane.

Figure 2. Intermetallic separations within the core of $\mathbf{1}$. Color code: $\mathrm{Co}^{\text {III }}$ brown, $\mathrm{Gd}^{\text {III }}$ yellow, N blue, O red.

Continuous Shape Measures calculations show that the $\left\{\mathrm{O}_{9}\right\}$ geometry around Gd 1 is closer to Muffin (MFF; CShM = 1.311) as compared to Spherical Capped Square Antiprism (CSAPR; $\mathrm{CShM}=1.570$ ) (Figure S 4 a and Table S 2 ). The triangular face comprising of $\mathrm{O} 3, \mathrm{O} 4$ and O 5 is utilized for the formation of the butterfly like topology. A similar observation is made for the $\mathrm{Ln}^{\text {III }}$ ions in 2 and $\mathbf{3}$ (see Table S 2 for CShM values). The $\mathrm{Co}^{\text {III }}$ centers on the other hand remain in a $\left\{\mathrm{N}_{2} \mathrm{O}_{4}\right\}$ distorted Octahedral environment (OC; CShM $=0.092$ (1), 0.087 (2), 0.101 (3)) (Figure S4b and Table S3). The amine N from $\mathrm{N}-\mathrm{BuDEA}^{2-}$ coordinates to the $\mathrm{Co}^{\mathrm{III}}$ ion trans to the N from $=\mathrm{N}^{-} \mathrm{O}^{-}$of $\mathrm{L}^{2-}$ with a longer $\mathrm{Co}-\mathrm{N}_{\mathrm{am}}$ distance (Co1-N2, 1.990(4) $\AA$ ) compared to the
$\mathrm{Co}-\mathrm{N}_{\mathrm{hyd} \text { am }}$ distance (Co1-N1, 1.870(4) $\AA$ ). Bond Valence Sum (BVS) ${ }^{39}$ analysis for localized bonds around the metal ion centers validated a formal valence state of + III for Co1 and Dy1. The numerous water and MeOH molecules present in the crystal lattice of $\mathbf{1}$ and $\mathbf{2}$ take part in extensive intermolecular hydrogen bonding interactions producing an infinite 3D network structure (Figure 3a). The O atoms from phenoxido ( O 1 ) and - $\mathrm{OMe}(\mathrm{O} 2)$ groups of $\mathrm{L}^{2-}$ trap a lattice water molecule ( O 6 W ) while a second water molecule ( O 5 W ) is trapped by the $\mu_{2}$ alkoxido arm (O5) from N-BuDEA ${ }^{2-}$ together with O1 (Pink lines in Figures 3a and 3b). Both O6W and O5W further show hydrogen bonding interactions with a third water molecule (O4W) and together form a hydrogen bonded $\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}$ cluster (Purple lines in Figures 3a and 3b) which connects the molecular units in one direction (Purple and pink lines in Figure 3a). Connection in the second direction is established through the hydrogen bonded interaction of a lattice water molecule (O2W) with the coordinated water molecule (O1W) and O8 of $\eta^{2}-\mathrm{Me}_{3} \mathrm{CCO}_{2}^{-}$(Green lines in Figures 3a and 3c). O2W also shows interaction with O5W of the $\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}$ cluster (Blue lines in Figure 3a). Another water molecule (O3W), hydrogen bonded to O4W, is further trapped by O1W and O 9 of $\eta^{2}-\mathrm{Me}_{3} \mathrm{CCO}_{2}^{-}$while a MeOH molecule (O10) shows interaction with this O3W as well as another MeOH (O10) thus connecting the molecular units in a third direction (Chrome yellow lines in Figure 3a and 3d). For the various parameters of the hydrogen bonding interactions refer to Table S4.

In contrast, the crystal lattice of $\mathbf{3}$ contains fewer water molecules and the hydrogen bonding interactions are far less extensive forming a 1D chain structure (Figure S5 and Table S4). Like in $\mathbf{1}$ and 2, the lattice water molecule, O 2 W , shows interaction with O 8 of $\eta^{2}-\mathrm{Me}_{3} \mathrm{CCO}_{2}{ }^{-}$and the coordinated water, O1W, connecting the molecular units in only one direction (Green lines in Figure S5). O1W and O 9 of $\eta^{2}-\mathrm{Me}_{3} \mathrm{CCO}_{2}^{-}$trap a MeOH molecule ( O 11 ) which in turn shows interaction with another MeOH ( O 10 ). A third MeOH molecule (O12) is trapped by O 1 (phenoxido O ) and O 5 ( $\mu_{2}$ alkoxido arm) which shows further interaction with O 2 W .

Figure 3. (a) Hydrogen bonded infinite 3D network structure formed with the help of lattice MeOH and $\mathrm{H}_{2} \mathrm{O}$ molecules in 1. (b) $\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}$ cluster connecting molecular units in one direction. (c) Connection of molecular units in second direction via hydrogen bonding interactions between O8, O2W and O1W. (d) Hydrogen bonding interactions between O3W, O10 (lattice MeOH ), O9, O1W and O4W connecting molecular units in third direction.
$\left[\mathrm{Ln}^{\mathrm{III}}{ }_{2} \mathrm{Co}^{\mathrm{II}} \mathrm{Co}^{\mathrm{III}}{ }_{2} \mathrm{~L}_{2}(\mathrm{~N}-\mathrm{BuDEA})_{2}\left(\mathrm{O}_{2} \mathrm{CCMe}_{3}\right)_{6}(\mathrm{MeOH})_{2}\right](\mathrm{Ln}=\mathrm{Dy}, 4 ; \mathrm{Ho}, 5)$. Both the complexes 4 and $\mathbf{5}$ crystallizes in monoclinic $C 2 / \mathrm{c}$ space group with $\mathrm{Z}=4$. Selected metric parameters are listed in Table S1. The neutral pentanuclear complexes consists of a $\left\{\mathrm{Ln}^{\mathrm{III}}{ }_{2} \mathrm{Co}^{\mathrm{III}}{ }_{2} \mathrm{Co}^{\mathrm{II}}\right\}$ core
having the general formula $\mathrm{Ln}^{\mathrm{III}}{ }_{2} \mathrm{Co}^{\mathrm{II}} \mathrm{Co}^{\mathrm{III}}{ }_{2} \mathrm{~L}_{2}(\mathrm{~N}-\mathrm{BuDEA})_{2}\left(\mathrm{O}_{2} \mathrm{CCMe}_{3}\right)_{6}(\mathrm{MeOH})_{2}$ formed with the help of two $\mathrm{L}^{2-}$ and two $\mathrm{N}-\mathrm{BuDEA}^{2-}$ anions. The crystal lattice was found to be devoid of any solvent molecules. The molecular structures of $\mathbf{4}$ and 5 are presented in Figure 4. Both complexes are isostructural in nature and thus the structural description is presented for the Dy derivative (4) as a representative case.

Figure 4. Molecular structures of $\mathbf{4}$ and $\mathbf{5}$ with atom numbering scheme and hydrogen atoms are omitted for clarity. Colour code: $\mathrm{Co}^{\text {III }}$ brown, $\mathrm{Co}^{\text {II }}$ pink, $\mathrm{Dy}^{\text {III }}$ violet, $\mathrm{Ho}^{\text {III }}$ turquoise, N blue, O red, C grey.

The coordination of $\mathrm{L}^{2-}$ and $\mathrm{N}-\mathrm{BuDEA}^{2-}$ anions to the $\mathrm{Co}^{\text {III }}$ ion is similar to that described for $\mathbf{1 -}$ 3. In contrast, the $\mu_{3}$ alkoxido arm of $\mathrm{N}-\mathrm{BuDEA}^{2-}$ connects a $\mathrm{Ln}^{\mathrm{III}}$ and a $\mathrm{Co}^{\mathrm{II}}$ ion (alongside $\mathrm{Co}^{\mathrm{III}}$ ) and not two $\mathrm{Ln}^{\text {III }}$ ions while the O end of the hydroxyl amine group of $\mathrm{L}^{2-}$, in its deprotonated $=\mathrm{N}-\mathrm{O}^{-}$form, bridges two $\mathrm{Ln}^{\text {III }}$ and the $\mathrm{Co}^{\text {II }}$ ion in a $\mu_{3}$ fashion. Thus an additional $\mathrm{Co}^{\mathrm{II}}$ ion, derived from $\mathrm{Co}_{2}\left(\mu-\mathrm{OH}_{2}\right)\left(\mathrm{O}_{2} \mathrm{CCMe}_{3}\right)_{4}\left(\mathrm{HO}_{2} \mathrm{CCMe}_{3}\right)_{4}$, is trapped in the structure of 4 and 5. The bridging nature of the other alkoxido arm of $\mathrm{N}-\mathrm{BuDEA}^{2-}$ is similar ( $\mu_{2}$ connecting $\mathrm{Co}^{\text {III }}$ and $\mathrm{Ln}^{\mathrm{III}}$ ) to $\mathbf{1}-\mathbf{3}$. The $\mathrm{Co}^{\mathrm{II}}$ ion is further connected to the $\mathrm{Co}^{\mathrm{III}}$ ions by two $\mathrm{Me}_{3} \mathrm{CCO}_{2}^{-}$anions, obtained from $\mathrm{Co}_{2}\left(\mu-\mathrm{OH}_{2}\right)\left(\mathrm{O}_{2} \mathrm{CCMe}_{3}\right)_{4}\left(\mathrm{HO}_{2} \mathrm{CCMe}_{3}\right)_{4}$, in $\mu_{1,3}$ fashion. Two more $\mathrm{Me}_{3} \mathrm{CCO}_{2}{ }^{-}$ anions shows $\mu_{1,3}$-bridging connection between the two $\mathrm{Ln}^{\text {III }}$ ions instead of connecting $\mathrm{Co}^{\text {III }}$ with $\mathrm{Ln}^{\text {III }}$ as observed in $\mathbf{1}-\mathbf{3}$ while two MeOH molecules coordinates to the $\mathrm{Ln}^{\mathrm{III}}$ in place of water. The $\mathrm{Ln}^{\text {III }}$ ions further coordinate a $\mathrm{Me}_{3} \mathrm{CCO}_{2}{ }^{-}$anion each, in $\eta^{1}$ fashion in contrast with $\eta^{2}$ in $\mathbf{1 - 3}$ giving a $\left\{\mathrm{O}_{8}\right\}$ distorted Square Antiprism geometry around them instead of $\left\{\mathrm{O}_{9}\right\}$.
The various intermetallic separations within the $\left\{\mathrm{Dy}_{2} \mathrm{Co}_{3}\right\}$ core of $\mathbf{4}$ are presented in Figure 5. The O end of $=\mathrm{N}-\mathrm{O}^{-}$showed greater variation in the two Dy1-O3 distances at 2.422(5) and $2.583(5) \AA$ compared to $\mathbf{1}-\mathbf{3}$ while the $\mathrm{Co} 2-\mathrm{O} 3$ distance is much shorter at $2.102(5) \AA$ (Figure

S6). The $\mu_{3}$ alkoxido arm of $\mathrm{N}-\mathrm{BuDEA}^{2-}$ also showed three different bond distances for Dyl$\mathrm{O} 4, \mathrm{Co} 2-\mathrm{O} 4$ and $\mathrm{Co} 1-\mathrm{O} 4$ at $2.537(5), 2.049(5)$ and $2.005(7) \AA$ while at the same time giving different M-O-M angles of $108.5(2)^{\circ}(\mathrm{Co} 1-\mathrm{O} 4-\mathrm{Co} 2)$, $94.26(18)^{\circ}(\mathrm{Co} 2-\mathrm{O} 4-\mathrm{Dy1})$ and $92.5(2)^{\circ}$ (Co1-O4-Dy1). The $\mu_{2}$ alkoxido arm recorded two Dyl-O5 and Co1-O5 distances at 2.306(6) and $1.880(6) \AA$ and a Co1-O5-Dy1 angle of $103.6(3)^{\circ}$. The three bridge angles for the O end of $=\mathrm{N}-\mathrm{O}^{-}$stands at $99.2(2)^{\circ}, 96.3(2)^{\circ}$ and $91.69(19)^{\circ}$ for $\mathrm{Dy} 1-\mathrm{O} 3-\mathrm{Dy} 1, \mathrm{Co} 2-\mathrm{O} 3-\mathrm{Dy} 1$ and $\mathrm{Co} 2-$ O3-Dy1. In contrast to 1-3 the overall disposition of the metal ion centers in 4-5 are not planar, rather the cobalt centers ( Co 1 and Co 2 ) are more or less collinear with the $\mathrm{Co}-\mathrm{Co}-\mathrm{Co}$ axis lying above the Dy-Dy axis. Thus the two planes containing one Col and two Dy1, each, make an angle of $82.18^{\circ}$ (Figure S7a) while those through Co1, Co2 and Dy1, Co2 are inclined at $50.25^{\circ}$ (Figure S7b).

Figure 5. Intermetallic separations within the core of 4. Color code: $\mathrm{Co}^{\text {III }}$ brown, $\mathrm{Co}^{\text {II }}$ pink, $\mathrm{Dy}^{\text {III }}$ violet, N blue, O red, C grey.

Continuous Shape Measures calculations show that the $\left\{\mathrm{O}_{8}\right\}$ geometry around Dy1 is closest to Square Antiprism (SAPR; CShM = 1.491) (Figure S8a and Table S2) with the two triangular faces comprising of O3, O4, O5 and O3, O3, O4 being utilized for the formation of $\left\{\mathrm{Dy}_{2} \mathrm{Co}_{3}\right\}$ core. The $\mathrm{Co}^{\mathrm{III}}$ and $\mathrm{Co}^{\text {II }}$ centers on the other hand remain in $\left\{\mathrm{N}_{2} \mathrm{O}_{4}\right\}$ and $\left\{\mathrm{O}_{6}\right\}$ distorted Octahedral environments ( OC ; $\mathrm{CShM}=0.436$, Co1 and 1.103, Co2) (Figures S8b and S8c and Table S3). Similar observations are made for 5 (see Tables S2 and S3 for values). As is evident from the CShM values, the $\mathrm{Co}^{\text {II }}$ center accommodates a higher distortion of the Octahedral geometry compared to $\mathrm{Co}^{\text {III }}$. Like $\mathbf{1 - 3}$, the amine N from $\mathrm{N}-\mathrm{BuDEA}^{2-}$ coordinates to the $\mathrm{Co}^{\text {III }}$ ion trans to the N from $=\mathrm{N}^{-} \mathrm{O}^{-}$of $\mathrm{L}^{2-}$ with a longer $\mathrm{Co}-\mathrm{N}_{\mathrm{am}}$ distance $(\mathrm{Col}-\mathrm{N} 2 \mathrm{~B}, 1.004(17) \AA$ ) compared to the $\mathrm{Co}-\mathrm{N}_{\mathrm{hyd}}$ am distance $\left(\mathrm{Co} 1-\mathrm{N} 1,1.893(6) \AA\right.$ ). Bond Valence Sum (BVS) ${ }^{39}$
analysis for localized bonds around the metal ion centers validated a formal valence state of + III for Co1 and Dy1, and +II for Co2.

The crystal lattices of $\mathbf{4}$ and 5 are devoid of any solvent molecules and hence no hydrogen bonded supramolecular structures are observed. Only intra molecular interaction is present between O 12 of the coordinated MeOH and O 11 of $\eta^{1} \mathrm{Me}_{3} \mathrm{CCO}_{2}^{-}$anions (Table S4).

## Rationale for the observed difference in structural types

In order to understand the effect of different sequence of ligand addition on the structure of the final compound, we have analyzed the HRMS (+ve) of the reaction mixtures (in MeOH ) for addition of $\mathrm{N}-\mathrm{BuDEAH}_{2}$ before $\mathrm{H}_{2} \mathrm{~L}$ and vice versa (Figures S 9 to S 16 ) in search of logical intermediates. Since both the structural types can be accessed for $\mathrm{Ln}^{\mathrm{III}}=\mathrm{Dy}{ }^{\mathrm{III}}$, analysis of the mass spectra of $\mathbf{3}$ and $\mathbf{4}$ gives information about the two aggregation processes.

The mass spectra for 3 revealed two peaks at $m / z=273.0982$ and $\mathbf{3 8 5 . 1 1 7 0}$ which can be assigned to the mononuclear $\mathrm{Co}^{\mathrm{II}}$ and $\mathrm{Co}^{\text {III }}$ species $\left\{\mathbf{C o}{ }^{\text {II }}(\mathbf{N}-\mathbf{B u D E A H})\left(\mathbf{H}_{2} \mathbf{O}\right)_{3}\right\}^{+}\left(\mathrm{C}_{8} \mathrm{H}_{24} \mathrm{CoNO}_{5}\right.$; calcd. 273.0986) and $\left\{\mathbf{C o}{ }^{\text {III }}(\mathbf{H L})(\mathbf{N}-\mathbf{B u D E A})\right\}^{+}\left(\mathrm{C}_{16} \mathrm{H}_{26} \mathrm{CoN}_{2} \mathrm{O}_{5}\right.$; calcd. 385.1174) respectively (Figure S13). Such mononuclear species (Scheme 3, species a and b) are formed by the initial coordination of $\mathrm{N}-\mathrm{BuDEAH}^{-}$to a $\mathrm{Co}^{\mathrm{II}}$ ion, after dissociation of $\mathrm{Co}_{2}(\mu-$ $\left.\mathrm{OH}_{2}\right)\left(\mathrm{O}_{2} \mathrm{CCMe}_{3}\right)_{4}\left(\mathrm{HO}_{2} \mathrm{CCMe}_{3}\right)_{4}$, followed by $\mathrm{HL}^{-}$leading to its oxidation when $\mathrm{N}-\mathrm{BuDEAH}_{2}$ is added before $\mathrm{H}_{2} \mathrm{~L}$. The mass spectra further exhibits a peak at $m / z=\mathbf{4 8 5 . 1 2 6 9}$ which can be assigned to the species $\left\{\left[\mathbf{D y}^{I I I}{ }_{2}\left(\mathbf{O}_{\mathbf{2}} \mathbf{C C M e}_{\mathbf{3}}\right)_{\mathbf{6}}\left(\mathbf{H}_{\mathbf{2}} \mathbf{O}\right)_{\mathbf{2}}\right]+\mathbf{2 H}\right\}^{\mathbf{2 +}}\left(\mathrm{C}_{30} \mathrm{H}_{60} \mathrm{Dy}_{2} \mathrm{O}_{14}\right.$; calcd. 485.1266). This points to the in-situ formation of dinuclear Dysprosium pivalate in reaction medium (Scheme 3). Previously we had reported the formation and presence of mononuclear $\operatorname{Ln}\left(\eta^{1}-\right.$ $\left.\mathrm{O}_{2} \mathrm{CCMe}_{3}\right)_{2}\left(\eta^{2}-\mathrm{O}_{2} \mathrm{CCMe}_{3}\right)_{2}\left(\mathrm{CH}_{3} \mathrm{OH}\right)_{2}{ }^{-}$counter anions within the crystal lattice. ${ }^{5}$ Trapping of the Dysprosium pivalate by two mononuclear species by extending a bridging coordination mode from the O atoms of alkoxido arms and $=\mathrm{N}-\mathrm{O}^{-}$group, lead to the formation of the tetranuclear Dy ${ }_{2}{ }_{2} \mathrm{Co}^{\text {III }}{ }_{2}$ complex (Scheme 3, intermediate $\mathbf{c}$ ). The $\mu_{1,3} \mathrm{Me}_{3} \mathrm{CCO}_{2}{ }^{-}$bridges between two $\mathrm{Dy}^{\text {III }}$ ions in Dysprosium pivalate are removed during such a process. The presence of complex $\mathbf{3}$ in solution is confirmed from the peak at $m / z=\mathbf{1 5 7 1 . 2 8 4 5}$ corresponding to $\left\{\left[\mathbf{D y}^{\mathrm{III}}{ }_{2} \mathbf{C o}^{\mathbf{I I I}}{ }_{2} \mathbf{L}_{\mathbf{2}}(\mathbf{N}-\right.\right.$ BuDEA $\left.\left.)_{\mathbf{2}}\left(\mathbf{O}_{\mathbf{2}} \mathbf{C C M e}_{3}\right)_{\mathbf{4}}\left(\mathbf{H}_{\mathbf{2}} \mathbf{O}\right)_{\mathbf{2}}\right]+\mathbf{K}\right\}^{+}\left(\mathrm{C}_{52} \mathrm{H}_{88} \mathrm{Co}_{2} \mathrm{Dy}_{2} \mathrm{KN}_{4} \mathrm{O}_{20}\right.$; calcd. 1571.2853).

Scheme 3. Proposed pathway for the formation of $\mathbf{3}$ in MeOH medium with $\mathrm{N}-\mathrm{BuDEAH}_{2}$ being added before $\mathrm{H}_{2} \mathrm{~L}$.

In the case of $\mathbf{4}$, the two peaks at $m / z=\mathbf{5 1 2 . 0 7 4 5}$ and $\mathbf{6 0 8 . 1 5 5 8}$ can be assigned to the dinuclear $\mathrm{Co}^{\mathrm{II}}{ }_{2}$ and $\mathrm{Co}^{\mathrm{II}} \mathrm{Co}^{\text {III }}$ species $\left\{\mathbf{C o}^{\mathbf{I I}} \mathbf{2}(\mathbf{H L})\left(\mathbf{O}_{2} \mathbf{C C M e} 3\right)(\mathbf{M e O H})_{4}\right\}^{+}\left(\mathrm{C}_{17} \mathrm{H}_{32} \mathrm{Co}_{2} \mathrm{NO}_{9}\right.$; calcd. 512.0741) and $\left\{\mathbf{C o}^{\mathbf{I I}} \mathbf{C} \mathbf{o}^{\mathrm{III}} \mathbf{L}(\mathbf{N}-\mathbf{B u D E A H})\left(\mathbf{O}_{2} \mathbf{C C M e} \mathbf{C O}_{3}\right)(\mathbf{M e O H})_{2}\right\}^{+} \quad\left(\mathrm{C}_{23} \mathrm{H}_{42} \mathrm{Co}_{2} \mathrm{~N}_{2} \mathrm{O}_{9} ;\right.$ calcd. 608.1554) respectively (Figure S14). Such dinuclear species (Scheme 4; species a and b) arise from the initial coordination of $\mathrm{L}^{2-}$ to $\mathrm{Co}_{2}\left(\mu-\mathrm{OH}_{2}\right)\left(\mathrm{O}_{2} \mathrm{CCMe}_{3}\right)_{4}\left(\mathrm{HO}_{2} \mathrm{CCMe}_{3}\right)_{4}$ followed by $\mathrm{N}-\mathrm{BuDEAH}^{-}$, leading to the oxidation of one cobalt center, when $\mathrm{H}_{2} \mathrm{~L}$ is added before $\mathrm{N}-\mathrm{BuDEAH}_{2}$. Thus unlike $\mathrm{N}-\mathrm{BuDEAH}_{2}($ in 3$)$, initial coordination of $\mathrm{H}_{2} \mathrm{~L}$ to $\mathrm{Co}_{2}\left(\mu-\mathrm{OH}_{2}\right)\left(\mathrm{O}_{2} \mathrm{CCMe}_{3}\right)_{4}\left(\mathrm{HO}_{2} \mathrm{CCMe}_{3}\right)_{4}$ results in preservation of its dinuclear structure. A peak at $m / z=\mathbf{1 0 2 9 . 2 7 2 4}$ can be assigned to
 calcd. 1029.2728) (Scheme 4; species $\mathbf{c}$ ) formed from two species $\mathbf{b}$ through the loss of a $\mathrm{Co}^{\text {II }}$ ion. Like in 3 , the peak at $m / z=\mathbf{4 8 5 . 1 2 6 9}$ corresponding to $\left\{\left[\mathbf{D y ~}^{\mathbf{I I I}}{ }_{2}\left(\mathbf{O}_{2} \mathbf{C C M e}_{3}\right)_{6}\left(\mathbf{H}_{2} \mathrm{O}\right)_{2}\right]+\mathbf{2 H}\right\}^{\mathbf{2 +}}$ points to the formation of dinuclear Dysprosium pivalate which is trapped by the species $\mathbf{c}$, through extension of bridging coordination mode from the O atoms of alkoxido arms and $=\mathrm{N}-\mathrm{O}^{-}$ group, leading to the formation of the pentanuclear $\mathrm{Dy}^{\mathrm{III}}{ }_{2} \mathrm{Co}^{\mathrm{II}} \mathrm{Co}^{\mathrm{III}}{ }_{2}$ complex (Scheme 4 ; intermediate d). Unlike in 3, the $\mu_{1,3} \mathrm{Me}_{3} \mathrm{CCO}_{2}^{-}$bridges between the two Dy ${ }^{\text {III }}$ ions in

Dysprosium pivalate remain intact during such a process. The peak at $\mathrm{m} / \mathrm{z}=\mathbf{9 3 3 . 6 9 2 3}$ corresponding to $\quad\left\{\left[\mathrm{Dy}^{\mathrm{III}}{ }_{2} \mathrm{Co}^{\mathrm{II}} \mathrm{Co}^{\mathrm{III}}{ }_{2} \mathrm{~L}_{2}(\mathrm{~N}-\mathrm{BuDEA})_{2}\left(\mathrm{O}_{\mathbf{2}} \mathrm{CCMe}_{3}\right)_{\mathbf{6}}(\mathrm{MeOH})_{2}\right]+\mathbf{2 N a}\right\}^{\mathbf{2 +}}$ $\left(\mathrm{C}_{64} \mathrm{H}_{110} \mathrm{Co}_{3} \mathrm{Dy}_{2} \mathrm{~N}_{4} \mathrm{Na}_{2} \mathrm{O}_{24}\right.$; calcd. 933.6925) confirms the presence of complex 4 in solution.

Scheme 4. Proposed pathway for the formation of 4 in MeOH medium with $\mathrm{H}_{2} \mathrm{~L}$ being added before $\mathrm{N}-$ BuDEAH $_{2}$.

For $\mathbf{1}$ and 2, when $\mathrm{N}-\mathrm{BuDEAH}_{2}$ is added first, the formation of both follows a pathway similar to 3 through intermediate e (Scheme S1, Path I). When $\mathrm{H}_{2} \mathrm{~L}$ is added first, the formed dinuclear species $\mathbf{d}$ (similar to that described for 4 ) looses a $\mathrm{Co}^{\text {II }}$ ion to give rise to mononuclear species $\mathbf{b}$ which results in $\mathbf{1}$ and $\mathbf{2}$ through intermediate e as shown for $\mathbf{3}$ (Scheme S1). In case of 5, for addition of $\mathrm{H}_{2} \mathrm{~L}$ before $\mathrm{N}-\mathrm{BuDEAH}_{2}$ (Scheme S 2 ; Path I), the aggregation pathway leading to its formation is similar to 4 . But when $\mathrm{N}-\mathrm{BuDEAH}_{2}$ is added before $\mathrm{H}_{2} \mathrm{~L}$ (Scheme S2, Path II), two of the formed mononuclear species $\mathbf{b}$ (similar to that described for $\mathbf{3}$ ) traps a $\mathrm{Co}^{\mathrm{II}}$ ion leading to
the trinuclear species $\mathbf{e}$ which follows the usual pathway as shown for 4. A detailed description for $\mathbf{1 , 2}$ and $\mathbf{5}$ is presented in ESI.

The impetus towards the transition from tetranuclear to pentanuclear structure across the lanthanide series is provided by the decreasing size of $\mathrm{Ln}^{\mathrm{III}}$ ions and their consequent preference for lower coordination numbers ( 9 for $\mathbf{1}-\mathbf{3}$ and 8 for $4-5$ ). The size of Dy ${ }^{\text {III }}$ is appropriate to access both the structural types.

## Magnetic Properties

The magnetic data for $\mathbf{1}$ are shown in Figure 6. Fitting the data for $\mathbf{1}$ required inclusion of a paramagnetic impurity term, which was fixed at a reasonable value ( $5 \%$ of a monomeric Co (II) impurity) by running a series of simulations in $\mathrm{PHI} .^{40}$ The $g$ value for $\mathrm{Gd}(\mathrm{IIII})$ was fixed to 2.0 and temperature independent paramagnetism (TIP) was fixed at $200 \times 10^{-6} \mathrm{~cm}^{3} \mathrm{~mol}^{-1} \operatorname{per} \mathrm{Co}$ (III) ion. ${ }^{41}$ Simultaneous fitting of the $\chi T$ vs. $T$ data and $M v s . H$ data in PHI gives: $J=-0.09( \pm 0.01)$ $\mathrm{cm}^{-1}$ (note that the obtained $J$ value is reported according to the Hamiltonian $\widehat{H}=-J\left(\vec{S}_{1} \cdot \vec{S}_{2}\right)$ to enable easy comparison to that obtained from the theoretical studies). Both the fit to the magnetic data and the DFT studies give a weak antiferromagnetic exchange interaction between the $\mathrm{Gd}(\mathrm{III})$ centres (vide infra). The $M$ vs. $H$ data arise largely from field-induced population of close-lying excited spin states within the complex due to the very weak exchange interaction between $\operatorname{Gd}($ III $)$ centers.

Figure 6. Temperature dependence of $\chi T$ for complex 1 (black open circles). The inset shows the magnetization $v s$. field data at 2,4 and 6 K . The solid lines correspond to a simultaneous fit of the susceptibility and magnetization data (see text for details).

The $\chi T$ vs. $T$ data for 2-5 are shown in Figure S24 and the fitting of that data is discussed in the section Theoretical Calculations. The $M v s . H$ data and the ac susceptibility data for 2-5 are shown in Figure S17 and Figures S18 to S21. The terbium(III)-containing complex 2 and holmium(III)-containing complex 5 display no slow relaxation of the magnetization with, or without, an applied dc field. The dysprosium(III)-containing complex $\mathbf{3}$ and the dysprosium(III)/cobalt(II)-containing complex 4 display the onset of slow relaxation of the magnetization at low temperature in zero dc field; there was no maxima observed upon addition of a dc field and no further ac studies could be carried out. The observed AC susceptibility behaviour for all complexes is consistent with the theoretical studies except for $\mathbf{3}$ and $\mathbf{4}$ (vide infra).

## Theoretical calculations

Contemporary approach to evaluate magnetic anisotropy and magnetic interactions in metal complexes is based on DFT and CASSCF calculations. First, DFT level of theory was utilized for assessing the isotropic exchange between two $\mathrm{Gd}^{\mathrm{III}}$ ions in compound $\mathbf{1}$ with the help of ORCA 4.2 software. Thus, the high-spin state and the broken-symmetry states were calculated with PBE0 hybrid functional using relativistic DKH basis sets for this version of Heisenberg spin Hamiltonian, $\widehat{H}=-J\left(\vec{S}_{1} \cdot \vec{S}_{2}\right)$, and the energy difference between high-spin (HS) and brokensymmetry (BS) spin states, $\Delta=E_{\mathrm{BS}}-E_{\mathrm{HS}}$, was found to be $\Delta=-4.306 \mathrm{~cm}^{-1}$. Subsequently, the exchange coupling $J$-parameter was calculated by Yamaguchi's approach ${ }^{42}$ as

$$
J=2 \Delta /\left(\left\langle S^{2}\right\rangle_{H S}-\left\langle S^{2}\right\rangle_{B S}\right) \cdots \text { (3) }
$$

and adopts value of $J=-0.18 \mathrm{~cm}^{-1}$, which suggests weak antiferromagnetic exchange and is consistent with the experimental finding. The calculated spin density of BS state is depicted in Figure 7.

Figure 7. The calculated spin density distribution using PBE0 for $\mathbf{1}$ for the broken-symmetry state. Positive and negative spin density is represented by yellow and cyan surfaces, respectively. The isodensity surfaces are plotted with the cut-off value of $0.02 \mathrm{ea}_{0}^{-3}$. Hydrogen atoms are omitted for clarity.

In case of compounds $\mathbf{2 - 5}$, the ground state properties of the lanthanides ions require CASSCF calculations in order to properly capture multireference character of these ions. Therefore, OpenMOLCAS package was used for CASSCF calculations, and modules SINGLE_ANISO and POLY_ANISO for evaluating the zero-field splitting and the analysis of mutual magnetic interactions, respectively. The active space of these calculations spans the respective $d$ or $f$ orbitals of $\mathrm{Co}^{\mathrm{II}}$ or $\mathrm{Ln}^{\mathrm{III}}$ ions. In case of $\mathbf{4}$ and 5, the molecular structures were simplified as shown in Figure S23b to make such calculations feasible. The results of CASSCF are depicted in Figure 8 , in which the zero-field splitting of the atomic terms induced by the ligand field is shown $-{ }^{7} \mathrm{~F}_{6}$ for $\mathrm{Tb}^{\text {III }},{ }^{6} \mathrm{H}_{15 / 2}$ for $\mathrm{Dy}^{\text {III }}$ and ${ }^{5} \mathrm{I}_{8}$ for $\mathrm{Ho}{ }^{\text {IIII }}$. Also, the levels of ${ }^{4} \mathrm{~T}_{1 \mathrm{~g}}$ ligand field term of $\mathrm{Co}^{\mathrm{II}}$ originating from $\mathrm{O}_{\mathrm{h}}$ symmetry of the ligand field split due to lowering the symmetry of the ligand field are shown in Figure 8. The respective energy levels and $g$-tensor values calculated with SINGLE_ANISO are listed in Tables S5 to S9. The calculations for $\mathrm{Tb}^{\text {III }}$ ion in $\mathbf{2}$ showed two almost energetically degenerate levels, followed by two other excited states located at 80-90 $\mathrm{cm}^{-1}$ (Table S5). Analogous situation is found also for $\mathrm{Ho}^{\text {III }}$ in 5 , where pseudo doublets can be identified and are separated by circa $20 \mathrm{~cm}^{-1}$ (Table S5). Both $\mathrm{Tb}^{\text {III }}$ and $\mathrm{Ho}^{\text {III }}$ ions are nonKramers ions, therefore tunneling gap ( $\Delta_{\text {tun }}$ ) within these pairs of states serves as indicator of the quantum tunneling of the magnetization. ${ }^{43}$ Unfortunately, $\Delta_{\text {tun }}$ is large for both $\mathrm{Tb}^{\text {III }}$ and $\mathrm{Ho}^{\text {III }}$ ions in 2 and 5 (Table S5), which could explain lack of slow relaxation of the magnetization in AC susceptibility data. In case of Dy ${ }^{\text {III }}$ ions of $\mathbf{3}$ and $\mathbf{4}$, the ground state possesses the axial type
of the magnetic anisotropy $\left(g_{z} \gg g_{x, y}\right)$, but the values of $g_{\mathrm{x}, \mathrm{y}}$ are larger than 0.00 , which indicates significant predisposition for the quantum tunneling of the magnetization confirmed also by relatively large values of transition magnetic moment matrix elements (Tables S6 to S7). Moreover, lowest excited states are very close, $66 \mathrm{~cm}^{-1}$ for $\mathbf{3}$ and $19.2 \mathrm{~cm}^{-1}$ for $\mathbf{4}$, which shows that local geometries of coordination polyhedra for these ions reduced the potential for large magnetization reversal barriers. This is also visualized in the plots of the magnetization blocking barrier for $\mathbf{3}$ and $\mathbf{4}$ produced by SINGLE_ANISO module (Figure S22). The axes of $g$-tensors are showed in Figure S23. Similarly, other Kramers type ions, Co ${ }^{\text {II }}$ in $\mathbf{4}$ and $\mathbf{5}$ have quite large $g_{x, y}$ parameters, which does not inhibit the quantum tunneling of the magnetization, thus despite the quite promising energies of the first excited states, $215 \mathrm{~cm}^{-1}$ in $\mathbf{4}$ and $202 \mathrm{~cm}^{-1}$ in $\mathbf{5}$, it is hard to expect their positive contribution to the slow relaxation of the magnetization (Tables S 8 to S 9 ).

Figure 8. The output of the CASSCF calculations with $\operatorname{CAS}(8,7)$ for $\mathrm{Tb}^{\text {III }}$ in $\mathbf{2}$, with $\operatorname{CAS}(9,7)$ for ${ }^{\text {D }}{ }^{\text {III }}$ in 3 and $\mathbf{4}$, with $\mathrm{CAS}(10,7)$ for $\mathrm{Ho}^{\mathrm{III}}$ in $\mathbf{5}$ and with $\mathrm{CAS}(7,5)$ for $\mathrm{Co}^{\mathrm{II}}$ in $\mathbf{4}$ and 5.

Next, we analyzed the experimental susceptibility data for $\mathbf{2 - 5}$ with the home-made routine in cooperation with POLY_ANISO module, ${ }^{44}$ and thus we were able to estimate $4 f-4 f$ and $3 d-4 f$ magnetic interactions in this series of the compounds. The results of fitting are depicted in Figure S24 and the values of parameters are summarized in Table 2. Weak ferromagnetic exchange between lanthanide ions $\left(J_{\mathrm{Ln}-\mathrm{Ln}}^{\mathrm{exch}}\right)$ were found in tetranuclear $\mathrm{Ln}^{\mathrm{III}}{ }_{2} \mathrm{Co}^{\mathrm{IIII}}{ }_{2}$ compounds, while antiferromagnetic exchange is present in pentanuclear $\mathrm{Ln}^{\mathrm{III}}{ }_{2} \mathrm{Co}^{\mathrm{II}} \mathrm{Co}^{\mathrm{IIII}}{ }_{2}$ (Table 2). The Co-Ln exchange is ferromagnetic in case of $\mathrm{Ln}=\mathrm{Dy}$, but was fitted antiferromagnetic for $\mathrm{Ln}=\mathrm{Ho}$. The variation of fitted parameters of magnetic exchange can be assigned to the variation of $f$-orbitals which are involved in mutual interactions. Moreover, we present the magnetization blocking
barrier calculated for compounds $\mathbf{3}$ and $\mathbf{4}$ for which out-of-phase signal of AC susceptibility was detected. The comparison of SINGLE_ANISO and POLY_ANISO calculations for $\mathbf{3}$ is showed in Figure 9. The matrix element of the transversal magnetic moment for $\mathrm{Dy}^{\mathrm{III}}$ ion of the lowest Kramers doublet is 0.097 which is close to the limit 0.1 used to determine effective tunneling of the magnetization from CASSCF calculations. Large transversal magnetic moments between ground state and the first excited state suggest that the effective energy barrier is limited to the first excited state ( $U_{\text {eff }} \leq 66 \mathrm{~cm}^{-1}$ ). Upon inclusion of dipolar and exchange Dy-Dy interactions, the lowest energy levels form pseudo doublets confirming prevailing antiferromagnetic interaction, $\left(J_{\text {tot }}=J_{\mathrm{Dy}-\mathrm{Dy}}^{\mathrm{exch}}+J_{\mathrm{Dy}-\mathrm{Dy}}^{\mathrm{dip}}\right)<0$, and diminishing but higher that threshold $\left(10^{-5} \mathrm{~cm}^{-1}\right)$ tunneling gaps ( $\Delta_{\text {tun }}=2.5 \times 10^{-3} \mathrm{~cm}^{-1}$ ). In case of compound 4, the SINGLE_ANISO calculations suggest significant probability for the tunneling of the magnetization (the matrix elements of the transversal magnetic moment between lowest Kramers doublets are larger than 0.1) and lowlying excited states. The incorporation of Dy-Dy and Co-Dy dipolar and exchange interactions by POLY_ANISO resulted in formation of three close lying Kramers doublets (Figure 10) and each of them having also significant probability for the quantum tunneling.

These outcomes are in contrast to the experimental observation of out-of-phase susceptibility in $\mathbf{3}$ and 4, however, we are aware that presented CASSCF calculations are not able to fully address all relaxation mechanisms in solid state. Differences between experimental and theoretically predicted data have also been highlighted in our previous work. ${ }^{6}$

Table 2. The magnetic exchange ( $J^{\mathrm{exch}}$ ) and dipolar interactions ( $J^{\text {dip }}$ ) derived from analysis of magnetic susceptibilities for 2-5 with POLY_ANISO module

| Types of magnetic <br> interaction $\left(\mathrm{cm}^{-1}\right)$ | $\mathbf{2}$ | $\mathbf{3}$ | $\mathbf{4}$ |  | $\mathbf{5}$ |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | $J_{\mathrm{Tb}-\mathrm{Tb}}$ | $J_{\mathrm{Dy}-\mathrm{Dy}}$ | $J_{\mathrm{Dy}-\mathrm{Dy}}$ | $J_{\mathrm{Co}-\mathrm{Dy}}$ | $J_{\mathrm{Ho}-\mathrm{Ho}}$ | $J_{\mathrm{C}-\mathrm{Ho}}$ |
| $J^{\text {dip }}$ | -0.089 | -0.177 | 0.000 | 0.000 | -0.025 | 0.000 |
| $J^{\text {exch }}$ | +0.002 | +0.122 | -1.602 | +3.180 | -0.020 | -0.390 |
| $J_{\text {tot }}$ | -0.087 | -0.055 | -1.602 | +3.180 | -0.045 | -0.390 |

Figure 9. Magnetization blocking barrier in $\mathbf{3}$ calculated for $\mathrm{Dy}^{\mathrm{III}}$ by SINGLE_ANISO (left) and for Dy ${ }^{\text {III }}$ Dy ${ }^{\text {III }}$ by POLY_ANISO using $J_{\mathrm{Dy}-\mathrm{Dy}}^{\mathrm{exch}}==+0.122 \mathrm{~cm}^{-1}$ and $J_{\mathrm{Dy}-\mathrm{Dy}}^{\mathrm{dip}}=-0.177 \mathrm{~cm}^{-1}(r i g h t)$. The numbers presented in plot represent the corresponding matrix element of the transversal magnetic moment, and the $\Delta_{\text {tun }}$ shows the tunneling gap of the indicated doublets.

Figure 10. Magnetization blocking barrier in 4 calculated for Dy ${ }^{\text {III }}$ by SINGLE_ANISO (left) and for Dy ${ }^{\text {III }}-\mathrm{Dy}^{\text {III }}-\mathrm{Co}^{\text {II }}$ by POLY_ANISO using exchange $\left(J^{\text {exch }}\right)$ and dipolar ( $J^{\text {dip }}$ ) interactions listed in Table 2 (right). The numbers presented in plot represent the corresponding matrix element of the transversal magnetic moment.

## Conclusions

The synthesis and isolation of five new cobalt-lanthanide coordination aggregates from the use of two different ligands $\mathrm{H}_{2} \mathrm{~L}$ and $\mathrm{N}-\mathrm{BuDEAH}_{2}$ together, has increased our understanding about the synthetic methods and the reaction sequences required to obtain such compounds. A shift in preference from tetranuclear to pentanuclear structure across the lanthanide series, projected,
the influence the size of the $\mathrm{Ln}^{\text {III }}$ ions can have on the nuclearity of coordination clusters and the consequent importance of the lanthanide contraction on the synthesis of polynuclear molecules. Furthermore the change in sequence of ligand addition opened up the pathway for accessing both structural types in the case of Dy ${ }^{\text {III }}$. HRMS (+ve) analysis of solutions revealed the differential cleavage of $\mathrm{Co}_{2}\left(\mu-\mathrm{OH}_{2}\right)\left(\mathrm{O}_{2} \mathrm{CCMe}_{3}\right)_{4}\left(\mathrm{HO}_{2} \mathrm{CCMe}_{3}\right)_{4}$ by the two ligands and helped understand the aggregation process under different sequence of reactant addition. The tetranuclear $\mathrm{Ln}^{\mathrm{III}}{ }_{2} \mathrm{Co}^{\mathrm{III}}{ }_{2}$ complexes exhibit a butterfly like topology with a more complex bridging network having the metal ion centers lying in a plane. On the other hand in the pentanuclear $\mathrm{Ln}^{\mathrm{III}}{ }_{2} \mathrm{Co}^{\mathrm{II}} \mathrm{Co}^{\mathrm{III}}{ }_{2}$ complexes, an additional $\mathrm{Co}^{\mathrm{II}}$ ion is trapped in the structure destroying the planar arrangement of the metal ions. Due to the presence of large number of solvent molecules within the crystal lattice of the $\mathrm{Ln}^{\mathrm{III}}{ }_{2} \mathrm{Co}^{\mathrm{III}}{ }_{2}$ aggregates, an extensive hydrogen bonding network was observed. Fitting of the magnetic data for $\mathbf{1}$ gives a weak antiferromagnetic exchange interaction between the $\mathrm{Gd}^{\text {III }}$ ions, which is confirmed by the theoretical calculations carried out with a PBE0 hybrid functional. The rest of the reported compounds were treated at CASSCF level of theory. Subsequent analysis of experimental magnetic data with POLY_ANISO module revealed variation of the dipole-dipole and the exchange interactions of the types $\mathrm{Ln}-\mathrm{Ln}$ and Ln -Co within the series suggesting fast relaxation of the magnetization. But this is in contrast to the out-ofphase signals observed in AC susceptibility measurements observed for $\mathbf{3}$ and 4. Theoretical predictions are in line with the experimentally observed lack of slow relaxation in $\mathbf{2}$ and $\mathbf{5}$.

## Electronic Supporting Information

X-ray crystallographic data in CIF format, Tables S1-S9, Figures S1-S24, Chart S1, Schemes S1-S2. CCDC-2090138, 2090137, 2090139, 2090141, 2090140 contain the supplementary crystallographic data in CIF format for complexes 1-5.
