78

79 Summary

80 A complete understanding of how environmental carcinogenic exposures promote cancer
81 formation is lacking. Over 70 years ago, tumour formation was proposed to occur in a two
82 step process: an initiating step which induces mutations in normal tissue, followed by a
83 promoter step which triggers cancer development. Recent evidence has revealed healthy
84 human tissue contains a patchwork of clones harbouring oncogenic mutations. This led us to
85 hypothesise that environmental particulate matter measuring $<2.5\mu\text{m}$ ($\text{PM}_{2.5}$), known to be
86 associated with lung cancer risk, might promote lung cancer by acting on pre-existing cells
87 harbouring oncogenic mutations in normal lung tissue. Focusing upon EGFR-driven lung
88 cancer, more common in never- or light-smokers, we observed a significant association
89 between $\text{PM}_{2.5}$ levels and the incidence of lung cancer in 371,543 individuals from UK
90 BioBank, resident at the same address for at least 3 years, and for 32,957 EGFR-driven lung
91 cancer cases in Public Health England, Taiwan Chang Gung Memorial Hospital, Korean
92 Samsung Medical Centre and the British Columbia Cancer Research Centre cohort.
93 Functional mouse models revealed that pollution causes an influx of macrophages into lung
94 epithelium and interleukin-1 β release, resulting in a progenitor-like cell state within EGFR
95 mutant lung alveolar type II epithelial cells that fuel and promote tumorigenesis, in a process
96 that can be attenuated with anti-interleukin-1 β . Ultradeep mutational profiling of histologically
97 normal lung tissue from 295 individuals across 3 clinical cohorts revealed oncogenic *EGFR*
98 and *KRAS* driver mutations in 18% and 53% of normal tissue samples, respectively. These
99 findings collectively support a tumour-promoting role for $\text{PM}_{2.5}$ acting on mutant clones in
100 normal lung tissue, providing support for public health policy initiatives to address air
101 pollution in urban areas to reduce disease burden.

102 Main text

103 Introduction

104 Barrier organs, such as the lung, are directly impacted by exposure to environmental
105 challenges. Accordingly, over 20 environmental and occupational agents are proven lung
106 carcinogens (IARC, 2015), and exposure to these are of particular relevance in
107 understanding lung cancer in the non-smoking population. Lung cancer in never smokers
108 (LCINS) is the 8th most common cause of cancer death in the UK¹ and has distinct clinical
109 and molecular characteristics compared to lung cancer in smokers². In particular, LCINS
110 frequently harbour EGFR oncogenic mutations which tend to be more frequent in female
111 patients, and in East Asian compared to Western patients³. Several plausible factors have
112 been proposed to explain the observed sex and geographical disparities of *EGFR* mutant
113 lung cancer, including germline genetics⁴, ethnicity, radon exposure, occupational
114 carcinogen exposure and air pollution⁵. While there is a clear tobacco-associated mutational
115 signature in lung cancer in smokers⁶, LCINS and EGFR-mutant lung cancers are
116 characterized as harbouring relatively few mutations⁷⁻¹¹ and LCINS has no mutational
117 signature reflecting a specific environmental exposure⁷ suggesting alternative mechanisms
118 of LCINS initiation.

119

120 Ambient air pollution in the form of particulate matter (PM) is categorized by size including
121 coarse particles with an aerodynamic-mass median diameter, 2.5-10 μm , (PM_{10}), fine
122 particles $<2.5 \mu\text{m}$, ($\text{PM}_{2.5}$) and ultrafine particles ($<0.1 \mu\text{m}$, $\text{PM}_{0.1}$). $\text{PM}_{2.5}$ is of major
123 importance given that approximately 99% of people live in areas that exceed the WHO
124 guideline $\text{PM}_{2.5}$ ($<5 \mu\text{g}/\text{m}^3$). Whilst air pollution levels vary widely between countries,
125 estimates suggest it is the world's fourth leading cause of death, accounting for 6.7 million
126 deaths in 2019, with communities with low socioeconomic status disproportionately exposed

127 to higher concentrations¹². Air pollution arises from a variety of sources including fossil-fuel
128 combustion and the burning of biomass for cooking, with particulate matter (PM) linked to
129 multiple health effects, including chronic obstructive pulmonary disease and asthma¹³.

130

131 Traditionally, it is thought that carcinogens cause tumours by directly inducing DNA
132 damage¹⁴. However, recent data from Balmain and colleagues, suggest that many
133 carcinogens do not cause a detectable DNA mutational signature in tumours following
134 exposure^{14,15}. A recent genetic analysis found that mutational signatures do not fully explain
135 the varied geographical incidence of oesophageal cancer¹⁶, and efforts that have profiled
136 LCINS tumour genomes failed to detect a dominant carcinogenic signal of mutations deriving
137 from exogenous sources^{7,11,17–19}. Furthermore, in the Sherlock study⁷ of lung cancer,
138 exogenous mutational signatures could only be identified in 3% of 232 LCINS genomes.

139

140 An alternative hypothesis for how environmental agents might act is by promoting cancer
141 development from initiated but dormant mutant cells²⁰. In the absence of exposure to a
142 promoting agent, DMBA-induced mutations in the skin remain dormant for most of the
143 lifespan of the mouse but rapidly progress following treatment with inflammatory stimulus²¹.

144 In support of the presence of such pre-existing mutant cells in normal tissues in humans,
145 sensitive deep sequencing approaches have revealed mutations in clones within normal
146 tissue from multiple organ sites, a minority of which are known to be driver oncogenic
147 mutations in tumours^{22–25}.

148

149 We hypothesised that air pollution might promote inflammatory changes in the normal tissue
150 microenvironment permitting mutated clones to expand and initiate tumours. To address this,
151 we combined epidemiological evidence with functional pre-clinical mouse cancer models,
152 and clinical cohorts providing access to normal lung tissue, to decipher potential
153 mechanisms of air pollution-induced lung tumour promotion and actionable targets for
154 molecular cancer prevention (Figure 1A).

155

156 Results

157 Frequency of EGFRm lung cancer correlates with PM_{2.5} levels across 158 global datasets

159 Our recently published analysis of the TRACERx 421 cohort revealed that despite a history
160 of smoking, a minority of LUADs (8%) lacked evidence of smoking-mediated mutagenesis,
161 including 6.4% of LUADs associated with >15 years of smoking²⁶. Consistent with this
162 analysis, 7-12% of smokers in the TRACERx 421 cohort do not have a driver SNV that can
163 be attributed to a smoking mutation signature (SBS4/SBS92) (Extended Data Figure 1A).
164 Taken together with work from Balmain and colleagues demonstrating that many
165 environmental carcinogens do not lead to a detectable mutagenic signature¹⁵, the question
166 arises as to how environmental carcinogens might facilitate cancer initiation in the absence
167 of detectable DNA mutagenesis. In order to address this question, we studied EGFR mutant
168 (EGFRm) lung cancer which has a high prevalence in LCINS (in England the probability of
169 having an EGFRm tumour in a LCINS patient is 36-40%) and because of the apparent
170 geographical disparities in its occurrence (Supplementary Table 1-3).

171

172 To examine the relationship between air pollution and EGFR mutant lung cancer incidence,
173 we used several ecological correlation analyses, acknowledging that these analyses only
174 provide estimates of incidence. We considered data from three countries to explore different
175 ranges of PM_{2.5} air pollution and ethnicities: England (92.06% Caucasian cohort; PM_{2.5} IQR:
176 9.95-11.2 µg/m³), South Korea (estimated >99% Asian cohort²⁷; PM_{2.5} IQR: 24.0-27.0
177 µg/m³) and Taiwan (estimated >98% Asian cohort⁴; PM_{2.5} IQR: 24.3-38.2 µg/m³). In each
178 country, there was a consistent relationship between PM_{2.5} levels (average concentration per
179 geographical area) and estimated EGFR mutant lung cancer incidence (Figure 1B-D). The

180 relative rates of EGFRm lung cancer incidence (per 100,000 population), per 1ug/m³
181 increment of PM_{2.5} were: England: 0.63 (p-value=0.0028), Korea: 0.71 (p-value=0.0091),
182 Taiwan: 1.82 (p-value=4.01e-06). In addition, when we restricted the England cohort to
183 adenocarcinoma cases, the relationship remained significant (Extended Data Figure 1B).

184

185 We were not able to account for migration of individuals prior to diagnosis of lung cancer. As
186 such, we obtained a female never-smoker, lung cancer (92% adenocarcinoma), cohort from
187 British Columbia, Canada, where PM 2.5 cumulative exposure was individually calculated for
188 each case via a detailed residential history from birth to current address, and input into
189 geographical information System mapping (GIS)²⁹. The majority of this cohort (83%) were
190 born outside of Canada and 46.7% were EGFR positive. An analysis of 3-year, high
191 compared with low PM 2.5 cumulative exposure and 20-year high compared with low PM_{2.5}
192 cumulative exposure (Methods) revealed the frequency of EGFRm in lung cancer cases was
193 significantly higher after 3 years of high air pollution exposure. (EGFRm frequency - 3 year:
194 High Pollution: 73%, Low Pollution: 40%, p-value=0.03). Of note, this was not observed after
195 20 years of high vs low cumulative exposure. 20 year: High Pollution: 50%, Low Pollution:
196 38%, p-value=0.35) (Extended Data Figure 1C). This suggests that 3 years of exposure may
197 be sufficient for EGFRm lung cancers to arise.

198

199 To explore if 3 years of cumulative PM_{2.5} exposure is associated with lung cancer (ICD: C33
200 and C34) in an independent cohort, we obtained data from 407,509 UK Biobank participants
201 (UKBB), where cancer incidence for 28 cancer types, residential location in the 3 years prior
202 to registration, and residential outdoor PM_{2.5} data for the year 2010 were available.

203

204 An analysis including all participants regardless of the consistency of residential location in
205 the 3 years prior to registration demonstrated that PM_{2.5} (calculated at 1 µg/m³ increments)
206 was associated with lung cancer incidence (Hazard Ratio = 1.08 (95% confidence interval
207 1.04-1.12); raw p-value=<0.001, FDR=0.001), consistent with a previous analysis of the

208 UKBB data from Huang et al³⁰ (Figure 1E; Supplementary Table S4). By contrast, lung
209 cancer incidence was not associated with outdoor radon levels (HR = 0.96 (0.89 - 1.03);
210 raw p-value=0.262). In addition, interaction tests between ever smoking status and PM_{2.5}
211 exposure suggest that smoking and high PM_{2.5} levels may have a combined effect on lung
212 cancer risk (p-value=0.049). We also noted nominal significance (raw p-value<0.05;
213 FDR>0.05) for lip and oropharyngeal cancer (HR = 1.10 (1.01-1.19); raw p-value=0.023;
214 FDR=0.215) and mesothelioma (HR = 1.11 (1.00-1.24), raw p-value=0.048, FDR=0.339).
215 While the estimated HRs from UKBB analyses are higher than in some population based
216 epidemiological surveys³¹, this may reflect, the over-representation of wealthier, never-
217 smoker individuals in UKBB (Methods). Finally, we restricted our analysis to participants
218 resident at the same address in the 3 years prior to registration (n=371,543) and observed
219 that the relationship between lung cancer incidence and PM_{2.5} exposure remained significant
220 (HR = 1.07 (1.03-1.11); p-value=<0.001).

221

222 Collectively, these data combined with published evidence demonstrating the relationship
223 between PM_{2.5} and LCINS²⁹, are consistent with an association between the estimated
224 incidence of EGFR mutant lung cancer and levels of PM_{2.5} exposure, and that at least 3
225 years of air pollution exposure may be sufficient for this association to manifest.

226 Air pollution promotes EGFR mutant lung cancer progression in mouse 227 models

228 We next used genetically engineered mouse models of lung adenocarcinoma to functionally
229 examine if PM exposure promotes lung tumour development. We induced expression of
230 oncogenic human *EGFR*^{L858R} mutations in lung tissue using intratracheal delivery of
231 adenoviral-Cre to mice engineered with *Rosa26*^{L^{SL}-tTa/LSL-tdTomato}; *TetO-EGFR*^{L858R} alleles (ET
232 mice). Following this, we delivered PBS control or fine PM, collected from an urban
233 environment with certified organic and inorganic components³² at physiologically relevant

234 doses³². Mice were given intratracheal administration of PM or PBS control three times per
235 week for three weeks after the induction of *EGFR*^{L858R} and tumour burden was assessed at
236 10 weeks post *EGFR*^{L858R} induction (Figure 2A). In this model, rare, sporadic lung epithelial
237 cells express oncogenic *EGFR* and expand to form pre-invasive neoplasia by 10 weeks
238 (Figure 2A,B). Analysis at 10 weeks of ET mice exposed to PM revealed a significant, dose-
239 dependent increase in the number of EGFR mutant cells that had undergone clonal
240 expansions to form neoplasia (control vs 5 µg p-value=0.047; control vs 50 µg p-
241 value=0.0007; Figure 2B). We further validated that PM is influencing epithelial cell tumour
242 formation by targeting *EGFR*^{L858R} specifically to alveolar type II (AT2) cells using adenoviral
243 SPC-Cre and exposing mice to 50 µg of PM. Exposure to PM was sufficient to significantly
244 increase the number of AT2 derived neoplasia (Extended Data Figure 2A). Exposure to PM
245 before the induction of EGFR mutation in ET mice using adenoviral CMV-Cre also resulted
246 in an increase in the number of early neoplasia (p-value=0.0241; Extended Data Figure 2B),
247 suggesting that PM exposure before or after oncogene induction is sufficient to promote
248 early EGFR mutant driven carcinogenesis.

249

250 We observed that PM also increased the number of adenocarcinomas in the more
251 aggressive *CCSP-rtTa; TetO-EGFR*^{L858R} model of doxycycline-inducible lung
252 adenocarcinoma (p-value=0.032; Extended Data Figure 2C), as well as the number of
253 hyperplasia in an adenoviral-Cre *Kras* model of lung cancer (*Rosa26*^{L^{SL}-tdTomato/+}; *Kras*^{L^{SL}-G12D/+}
254 (KT); 5 µg p-value=0.048; 50 µg p-value=0.0087; Extended Data Figure 2D). Together, these
255 data suggest that PM can promote tumour progression in both oncogenic *Kras* and *EGFR*-
256 driven models of lung adenocarcinoma.

257

258 Next we explored the mechanisms by which PM might promote *EGFR* mutant lung
259 tumourigenesis. Spatial analysis of clonal dynamics throughout early tumourigenesis in ET
260 mice exposed to PM after induction of *EGFR*^{L858R} (Figure 2C, see Methods), indicated that
261 *EGFR* mutant cell expansion is not observed during PM exposure but manifests in the period

262 after PM cessation (p-value=0.0131, Figure 2D); the fraction of EGFR^{L858R} cells that grew
263 into clusters and the number of cells within these clusters were both significantly increased
264 in PM exposed ET mice at 10 weeks but not at 3 weeks (p-value=0.253, Figure 2E). These
265 data suggest PM acts in two ways to promote early tumourigenesis; by increasing the
266 number of EGFR mutant cells with the potential to form a tumour and by elevating the
267 proliferation rate of EGFR mutant cells within these early tumours.

268

269 To test if PM promotes tumourigenesis through DNA mutagenesis within epithelial tumour
270 cells, we performed whole genome sequencing (WGS) on tumours from ET mice exposed to
271 50ug of air pollution (n=5), and PBS controls (n=5). We did not observe a significant
272 increase in the number of mutations in tumours from pollution exposed mice (p-
273 value=0.304), nor enrichment in established single base substitution (SBS) signatures (p-
274 value=0.989), suggesting that short term exposure to PM does not enhance mutagenesis
275 (Extended Data Figure 3). The majority of the mutations in tumours from pollution exposed
276 and control mice were attributable to the ageing signature (Extended Data Figure 3). We
277 next examined if the immune system was required for PM-enhanced EGFR mutant
278 tumourigenesis. We crossed *Rosa26*^{LSL-tTa}; *TetO-EGFR*^{L858R} mice with *Rag2*^{-/-}; *Il2rg*^{-/-} mice
279 which lack T, B, NK cells and have an altered myeloid compartment³³ to generate immune-
280 deficient EGFR mutant mice upon intratracheal delivery of adenoviral Cre (*Rag2*^{-/-}; *Il2rg*^{-/-}
281 ; *Rosa26*^{LSL-tTa/+}; *TetO-EGFR*^{L858R}). Unlike in the ET mice (Figure 2B), 3 weeks of exposure to
282 PM did not result in a significant increase in neoplasia following *EGFR*^{L858R} induction
283 compared to PBS control mice, suggesting a competent immune system is required for PM-
284 enhanced EGFR mutant lung tumourigenesis (p-value=0.879; Figure 2F).

285

286 The inhalation of toxic particles induces a local response in the lung which is mediated by
287 macrophages as well as lung epithelial cells^{34,35}. We profiled the acute myeloid response to
288 PM in immune competent lungs harbouring EGFR mutant cells (ET mice) or control (T mice,
289 *Rosa26*^{LSL-tdTomato/+}) 24 hours after the final PM exposure. We observed an increase in the

290 proportion of interstitial macrophages (IMs)(T p-value=0.0427, ET p-value=0.0335 Figure
291 2G,) and the expression of PD-L1 upon these cells in both T and ET mice following 50µg PM
292 exposure (T p-value=0.0309, ET p-value=0.0061; Figure 2H). Following PM exposure, there
293 was no difference in the proportion of alveolar macrophages (AMs) in the lung (Extended
294 Data figure 4A). There was a significant increase in neutrophils in T mice only and dendritic
295 cells were only elevated in ET mice (Extended Data Figure 4A). Immunofluorescence
296 staining of ET lungs with the pan-macrophage marker CD68 revealed increased density of
297 CD68+ macrophages with PM exposure both acutely and 7 weeks post exposure (3 weeks
298 p-value=<0.0001; 10 weeks p-value=0.0217; Figure 2I). These data suggest transient
299 treatment with PM leads to a sustained increase of PM-associated macrophages throughout
300 early tumorigenesis. We also observed this sustained increase in macrophages in both the
301 doxycycline inducible EGFR^{L858R} model and the KT model at 10 weeks post induction
302 (Extended Data Figure 4B,C) and confirmed these were CD11b+; CD68+ interstitial
303 macrophages (Extended Data Figure 4D). These data support the hypothesis that transient
304 PM exposure is associated with enhanced and sustained lung macrophage infiltration,
305 beyond the time of PM exposure.

306 Elevated progenitor-like ability of EGFR mutant AT2 cells upon PM 307 exposure

308 Next, to understand how PM affects lung epithelium, we carried out RNA-seq of flow purified
309 lung epithelia following exposure to four conditions; reporter T mice exposed to PM (T-PM)
310 or PBS control (T), and ET mice exposed to PM (ET-PM) or PBS control (ET). Using
311 principal components (PC) analysis we observed that PM induced significant alterations in
312 the epithelial transcriptome from both T and ET mice, with PM accounting for 19% of the
313 variance in differentially expressed genes (genes differentially expressed between T-PM and
314 T display higher PC2 ranks, p-value<0.001) and EGFR mutation accounting for 38% of the
315 variance (genes differentially expressed between ET and T display higher PC1 ranks, p-

316 value<0.001) (Figure 3A), (Supplementary Table S5). Gene set enrichment analysis of ET
317 mice exposed to PM compared to ET control mice revealed that IL6-JAK-STAT,
318 inflammatory response and allograft rejection pathways were uniquely upregulated upon
319 exposure to PM in EGFR-mutant epithelium in comparison to T mice (Figure 3B; Extended
320 Data Figure 5A). In particular, we observed upregulation of genes known to regulate
321 macrophage recruitment (interleukin-1 β (IL1 β), GM-CSF, CCL6 and NF-Kb) and the
322 epithelial-derived alarmin (IL33) in PM exposed mouse epithelia (Figure 3C). Lung injury
323 models in mice can induce cell state changes within a proportion of AT2 cells, a likely cell of
324 origin of lung adenocarcinoma³⁶, and expand populations with a progenitor-like phenotype
325 which mediate alveolar regeneration, and can be driven by inflammatory signals such as
326 IL1 β ^{37,38}. Consistent with our data showing that PM can promote tumorigenesis from
327 EGFR^{L858R} mutant AT2 cells, we noted upregulation of genes previously associated with
328 altered, progenitor-like AT2 cell states in PM treated mouse epithelial tissue (Figure 3C). In
329 addition, deconvolution of single cell signals trained on mouse lung scRNA-seq of bleomycin
330 treated mouse lungs³⁹ identified a significantly increased Krt8+ AT2 progenitor state score
331 only in ET mice exposed to PM (Extended Data Figure 5B) suggesting EGFR^{L858R} mutant
332 AT2 cells are transcriptionally reprogrammed to this progenitor cell state with PM exposure.
333 We compared the mouse RNA-seq data to a human clinical crossover study, in which
334 lung brushings from people who had never smoked were taken after exposure to diesel
335 exhaust and filtered air^{40,41}. A number of gene expression changes, significantly up-
336 regulated in mouse lung epithelium were also up-regulated in human lung epithelium
337 (but not reaching significance in this small human cohort) after PM exposure including
338 IL1 β , IL1a markers of macrophage recruitment and ORM1 and LRG1 markers of the
339 AT2 cell state (Extended Data Figure 5C,D). The details of each gene in this
340 comparison are detailed in Supplementary Table S5.

341

342 These results identify PM induced inflammatory pathways in mice and humans and
343 transcriptional changes associated with lung progenitor cell states³⁷. To test if these
344 transcriptional changes are reflected in functional differences in epithelial cell progenitor
345 behaviour following PM exposure, we performed a lung organoid formation assay⁴² in which
346 lung epithelial cells from ET mice were isolated and grown as 3D organoids *ex vivo* following
347 *in vivo* exposure to PM (Figure 3D). Non-recombined cells from ET mice exposed to PM did
348 not display a significant increase in organoid formation efficiency (OFE)(p-value=0.0747;
349 Figure 3E). In contrast, recombined, tdTomato+ *EGFR*^{L858R} cells exposed to PM
350 demonstrated a more pronounced and significant increase in OFE (p-value=0.0245; Figure
351 3E). To validate whether specifically AT2 cells are functionally altered by PM, we flow
352 purified AT2 cells from non-induced ET or T mice exposed to PM, according to published
353 protocols⁴³, and subsequently performed adenoviral-Cre recombination *in vitro*⁴⁴ in order
354 to express *EGFR*^{L858R} and *tdTomato* or just the reporter control, before plating in the
355 organoid assay (Extended Data Figure 5E). We observed significantly elevated OFE only in
356 tdTomato+ *EGFR*^{L858R} AT2 cells from mice exposed to PM *in vivo* (p-value=0.0043;
357 Extended Data Figure 5F, G), consistent with our *in vivo* data (Extended Data Figure 2A,D)
358 demonstrating that the AT2 cell is a PM-vulnerable lung cancer cell of origin and that
359 reversing the order of oncogene mutation initiation and PM exposure does not appear to
360 impact tumour initiation capacity. Immunofluorescence confirmed the organoids expressed
361 markers of Krt8+ SPC+ AT2 progenitor states (Extended Data Figure 5H). These data
362 suggest that the combination of *in vivo* exposure of AT2 cells to PM and induction of the
363 *EGFR*^{L858R} driver mutation increases AT2 cell progenitor function, a phenotype that is not
364 seen with PM exposure or expression of *EGFR*^{L858R} alone.

365

366 We previously observed an enrichment of interstitial macrophages in lung epithelium
367 following PM exposure (Figure 2I). Consistent with these data, we observed an increase in a
368 macrophage-recruitment geneset in PM exposed mouse epithelium (figure 3C). We

369 hypothesised that lung macrophages, which generate inflammatory mediators when
370 exposed to particulate matter³⁵, might be central to the tumour promotion step. To assess
371 whether pollution exposed macrophages are sufficient to drive increased OFE of non-PM
372 exposed AT2 cells, PBS-treated AT2 cells expressing *EGFR*^{L858R} *ex vivo* were co-cultured
373 with either *in vivo* exposed PM or PBS macrophages (Figure 3F). Both PM-exposed
374 interstitial and alveolar macrophages significantly increased the OFE of EGFR mutant AT2
375 cells (paired t-test, IMs p-value=0.0095; AMs p-value=0.0002; Figure 3G) suggesting a key
376 mediator of PM-induced inflammation arises from macrophages.

377

378 Previous reports suggest IL1 β derived from lung macrophages is required for the formation
379 of Krt8+ AT2 progenitor cells after bleomycin injury³⁷, and we noted up-regulation of IL1 β in
380 the mouse transcriptomic data following PM exposure (figure 3C), hence we reasoned IL1 β
381 may be a key molecular mediator of this pollutant-driven cell state change. We confirmed
382 IL1 β is induced by PM using RNAscope and is predominantly arising in CD68+
383 macrophages (Extended Data Figure 5 I,J). Next, we explored whether treatment with IL1 β
384 is sufficient to promote expansion of EGFR mutant organoids. AT2 cells were isolated from
385 naive ET mice, followed by oncogene activation *in vitro* and plated in the organoid assay
386 with IL1 β added to the media. This resulted in an expansion of organoid size, with organoids
387 maintaining expression of Krt8+ SPC+ AT2 progenitor states (Extended Data Figure 5K).
388 Finally, to test the requirement of IL1 β for PM-mediated adenocarcinoma formation we
389 initiated oncogene expression in the doxycycline inducible *CCSP-rtTa; TetO-EGFR*^{L858R}
390 model; then exposed them to 50 μ g of PM and administered anti-IL1 β or control antibody
391 (8mg/kg/week) during this exposure period (Figure 3H). We found that at 10 weeks post-
392 induction, *EGFR*^{L858R} mutant mice treated with anti-IL1 β during exposure to PM had
393 significantly attenuated lung adenocarcinoma formation (Figure 3I). Collectively, these data
394 suggest PM exposed macrophages are sufficient to drive a progenitor-like state in EGFR
395 mutant AT2 cells, macrophages are a key source of IL1 β in response to PM *in vivo* and IL1 β
396 signalling is required for the promotion of PM-mediated EGFR mutant lung adenocarcinoma.

397 *EGFR* and *KRAS* mutations are common in normal lung tissue

398 If tumour development does occur via two steps as originally proposed by Berenblum⁴⁵,
399 initiation and promotion, this is contingent on histologically normal tissue cells harbouring
400 oncogenic driver mutations²⁰. In 15 reported studies involving deep sequencing of human
401 histologically normal tissues from different anatomic sites (n=9380 samples from 380
402 patients), an oncogenic *EGFR*^{L858R} mutation was only reported in 1 clone from a skin
403 microbiopsy, suggesting these mutations are rare in well-profiled organs such as the skin,
404 oesophagus, bladder and liver. (Supplementary Table S6). Therefore, we sought evidence
405 for *EGFR* driver mutations in normal lung tissue in people with lung cancer, cancers of other
406 organ sites and individuals with no evidence of cancer, using digital droplet PCR (ddPCR) or
407 Duplex-seq (Figure 4A, Extended Data Figure 7, Supplementary Table S7). Specifically, we
408 only considered mutations that were distinct from those present in matched lung tumours for
409 patients with a history of lung cancer.

410

411 We selected normal lung tissue from 195 of 1346 prospectively recruited patients in
412 TRACERx (NCT01888601), balancing the cohort for sex (Female n=96; Male n=99), *EGFR*
413 mutant tumour status (*EGFR* mutant driver n=39; Other *EGFR* mutant n=10; *EGFR* wt n=
414 146), smoking status (Ever Smoked n=150; Never Smoked n=45), all within the limits of
415 tissue availability (Figure 4A; Supplementary Table S7, Extended Data Figure 7,8A). We
416 used ddPCR to detect the presence of 5 specific oncogenic *EGFR* driver mutations
417 (Exon19del, G719S, L858R, L861Q, S768I (Klughammer et al., 2016)), and to identify
418 possible clonal expansions in normal lung tissue. The achievable limit of detection was
419 0.004% based on available input DNA (approximately 600ng per assay).

420

421 To exclude the presence of clonal or subclonal spatially distinct *EGFR* mutations that may
422 be present in the corresponding matched lung tumour, we performed multi-region deep next
423 generation sequencing of non-small cell lung cancer (NSCLC) from the same patients

424 (>3000x coverage) of 19 driver genes (including *EGFR*) using the MiSeq platform. We
425 sequenced 751 tumour regions from the 195 tumours (median 3 regions/tumour) with an
426 achievable limit of detection in each tumour region of 0.966% based on a median
427 sequencing depth per region of 3490X and a MiSeq error rate of 0.473%⁴⁶.

428

429 We filtered out occurrences of the same mutation in both tumour and normal tissue,
430 potentially attributable to contamination from the primary tumour. After filtering, 38/195 (19%)
431 patients harboured activating *EGFR* mutations exclusively in normal lung tissue that were
432 not detectable in tumour tissue (Figure 4A,B). In tumours from these patients with
433 corresponding normal tissue samples harbouring *EGFR* mutations, we noted clonal driver
434 mutations in other genes: *TP53*, *PIK3CA*, *KRAS*, *ERBB2*, *CDKN2A*, *BRAF*, and *AKT1*. In
435 patient CRUK267, both *EGFR* L858R and *EGFR* L861Q were detected in normal lung, but
436 only *EGFR* L861Q (the less common driver mutation) was found in the tumour. These
437 findings indicate that *EGFR* driver mutations can be present in normal lung tissue, even in
438 patients where the same mutations were not selected during NSCLC tumourigenesis.

439

440 To examine whether *EGFR* mutations exist in normal lung tissue from people who never
441 develop lung cancer in their lifetime, we profiled 59 normal lung samples (median 3
442 samples/patient) collected at autopsy from the PEACE (NCT03004755) study - 19 patients
443 who died of other cancers: Melanoma (n=12), Ovarian Cancer (n=1), Renal Cancer (n=3),
444 Sarcoma (n=2), Mesothelioma (n=1) (Figure 4A, Supplementary Table S7, Extended Data
445 Figure 7,8A). An *EGFR* driver mutation was detected in the normal lung of 16% (3/19)
446 patients (Figure 4B). Despite spatially separated multi-region ddPCR analysis of normal
447 tissue in 15 of the 19 patients, in patients where *EGFR* driver mutations were detected, they
448 were only detected in one region. Based on the frequency of oncogenic *EGFR* driver
449 mutations identified in PEACE and TRACERx normal lung samples, we estimated the
450 mutation rate of the individual 5 *EGFR* mutations using Bayesian inference. (Methods) This
451 yielded a rate of 1 in 2,035,000 (95% credible interval: 1 in 805,000 to 1 in 3,040,000).

452 Combining these rates to obtain an average EGFR mutation rate, allowed us to estimate that
453 an EGFR oncogenic driver mutation would be present in 1 in 554,500 cells (or around
454 1:600,000 cells).(Methods)

455

456 We next addressed whether there was an association of oncogenic *EGFR* mutations within
457 normal tissue and exposure to ambient pollution in this TRACERx cohort. Anthracosis,
458 determined by the presence of anthracotic pigment (Extended Data Figure 8B), can act as a
459 surrogate for exposure to ambient air pollution⁴⁷. We classified anthracosis within the normal
460 tissue lung samples with and without *EGFR* activating mutations (Figure 4C-D). While there
461 was no association between the presence of an *EGFR* driver mutation in normal tissue and
462 anthracosis (Figure 4C, Prop.test p-value=0.39), there was a significant association between
463 anthracosis and elevated variant allele frequencies of *EGFR* driver mutations (Figure 4D, T-
464 test p-value=0.015). Although there is a trend towards enrichment of smokers in the
465 anthracosis position group (Fisher's exact test, p = 0.065), there are several reports⁴⁷⁻⁴⁹ that
466 suggest that cigarette smoking is not a risk factor for anthracosis. Moreover, in our cohort
467 the degree of anthracosis observed in never smokers and smokers does not differ;
468 suggesting smoking is not associated with anthracosis (p-value=0.43; Extended Data Figure
469 8C). While there are multiple environmental contributors to anthracosis⁴⁷, these data suggest
470 pollutants are not associated with the frequency of activating oncogenic mutations but rather
471 are associated with the expansion of EGFRm clones.

472

473 We sought to validate the identification of EGFRm using an independent ultra-deep
474 sequencing platform in additional cohorts of patients (n=81) with and without cancer,
475 addressing whether driver mutations existed at other genomic loci in *EGFR* and *KRAS*.
476 Using Duplex-seq, we analysed an additional 48 normal lung tissue samples from the
477 PEACE study (NCT03004755) (lung cancer n=9; other cancer n=39), and 33 normal lung
478 tissue samples derived from the Biomarkers and Dysplastic Respiratory Epithelium

479 (BDRE) Study (NCT00900419, Figure 4A, Supplementary Table S7, Extended Data Figure
480 7). The BDRE Study cohort consisted of patients with suspicious lung nodules who were
481 referred for evaluation by navigational bronchoscopy at the site of the CT detected lesion
482 (involved site). For each patient, a brushing from the contralateral lung, enriched for
483 bronchial epithelial cells (>89%,^{50,51}), was taken for research purposes and used as the
484 source of normal tissue for Duplex-seq. From the BDRE Study cohort, we profiled normal
485 samples from 20 patients with confirmed malignancy in the contralateral lung (lung
486 adenocarcinoma n=10 (including 2 never smokers); lung squamous cell carcinoma n=7;
487 other lung cancer n=2; renal cancer n=1) and normal samples from 13 people without a
488 subsequent cancer diagnosis (including 2 never smokers).

489

490 Profiling was carried out using Duplex-seq which identifies mutations within the *EGFR*
491 tyrosine kinase domain exons 18, 19, 20, and 21, *KRAS* GTP binding domain exons 2 and 3,
492 and loci from 29 other genes, with a limit of detection of <0.01%. Given the broader
493 spectrum of *EGFR* mutations detected by Duplex-seq across several exons, we only
494 considered mutations featured in the cancer gene census⁵², and further filtered mutations by
495 evidence of driver mutation status in the literature (Supplementary Table S8). In 24 of 68
496 cancer cases where tissue was available, we also performed Duplex-seq or MiSeq on the
497 corresponding tumour tissue to confirm that the mutations present in normal tissue were
498 found exclusively in the normal tissue samples. Based on the Duplex-seq data, 13/81 (16%)
499 samples harboured an *EGFR* driver mutation (E709X, G719X, T725M, Exon 19 del, R765X,
500 R776X, L858R, L861X; Figure 4E, Extended Data Figure 9A), while 43/81 (53%) samples
501 harboured a *KRAS* driver mutation (G12X, G13X, Q61X; Figure 4E, Extended Data Figure
502 9B,C). BRAF inhibitors, used to treat BRAFm melanomas, are known to promote
503 accelerated growth of clones harbouring RAS mutations⁵³. To exclude the possibility of
504 BRAF inhibitor treatment confounding our analysis, we excluded all melanoma patients from
505 analysis and this did not change the percentage of cases harbouring a KRASm 36/68 (53%).
506 Of note, in samples from smokers from the Duplex-seq PEACE cohort, high confidence (var

507 count \geq 2) KRAS mutation VAFs were significantly higher than EGFR mutation VAFs
508 (Extended Data Figure 9D, p-value=0.012). Moreover, in the 4 cases that harboured high
509 confidence driver mutations in both KRAS and EGFR, VAFs of KRAS mutations were
510 consistently higher than those in EGFR (Extended Data Figure 9D, paired t-test = 0.01513),
511 suggesting that when KRAS_m clones and EGFR_m clones are both present in normal lungs
512 of smokers, KRAS_m clones may be more highly selected than EGFR_m clones.

513

514 In summary, Duplex-seq and ddPCR revealed that 54/295 (18%) of normal lung samples
515 harboured an *EGFR* driver mutation, and 43/81 (53%) normal lung samples harboured a
516 *KRAS* driver mutation. We note that a limitation of our profiling strategies is that we have not
517 purified epithelial cells, the initiating cells of lung tumours, and further work would be
518 required to pinpoint which lineages harbour these mutations. From histological analysis,
519 AT2/AT1 cells account for on average 22% of distal lung parenchyma cells in autopsy or
520 surgical resection lung samples, mixed with 37% endothelial cells, 37% interstitial cells and
521 3% macrophages⁵⁴. When we compared proportions of samples that harboured *EGFR* or
522 *KRAS* mutations, no significant trends between smoking status or cancer diagnosis was
523 observed (Supplementary Table S12). We addressed whether mutation signals could be
524 deduced that might shed light on the preponderance of EGFR_m LCINS in females. Smoking
525 status, sex, anthracosis and age of patients in the ddPCR TRACERx cohort were entered
526 into a multivariable model to determine which best predicted the likelihood of an EGFR
527 mutation present in normal tissue. Female sex demonstrated the strongest association (p-
528 value=0.06; Extended Data Figure 8D). In order to address whether oncogenic mutations
529 accumulate with the natural ageing process we examined driver mutation frequency
530 harboured by all 31 genes (including EGFR and KRAS) in the Duplex-seq panel in the 17
531 never smoker patients and noted a significant correlation between age and mutation count in
532 the PEACE cohort (Figure 4F) supporting prior work^{25,55}.

533

534 In summary, these data suggest that oncogenic mutations are present in normal tissue at
535 low frequency and increase with age, fulfilling the initiating step of the Berenblum model. PM
536 results in infiltration of macrophages and release of inflammatory mediators into lung
537 epithelium, including IL1 β , which augment progenitor activity of AT2 cells only if these cells
538 harbour an activating oncogenic mutation, fulfilling Berenblum's tumour promoter step.

539 Discussion

540 70 years ago, Berenblum and Shubik developed the concept of two processes involved in
541 carcinogenesis; tumour initiation and tumour promotion, the latter involving exposure to an
542 inflammatory but non-mutagenic agent. In the absence of a promotion phase, initiated cells
543 remain dormant for most of the lifespan of a mouse²⁰. Balmain and colleagues studied
544 squamous cell carcinoma tumour development in the mouse, showing that cancer
545 development is driven by initiated cells, harbouring DMBA-induced oncogenic mutations in
546 histologically normal tissues, with subsequent inflammatory stimulus in the form of TPA
547 drives tumour promotion and overt malignancy^{21,56}. A number of risk factors have been
548 identified for LCINS including second-hand smoke, occupational carcinogen exposure,
549 germline genetics⁴ and radon exposure⁵. In this study, we explored the paradigm of tumour
550 promotion driven by particulate matter in the development of lung cancer by air pollutants.

551

552 Controlled human exposure studies have found acute diesel exhaust exposure can promote
553 airway inflammation⁵⁷. The IARC monographs 105⁵⁸ and 109⁵⁹ propose that diesel and
554 gasoline engine exhausts, and outdoor pollution induce lung tumours via genotoxicity,
555 induction of oxidative stress and inflammation. In our manuscript, we build on these previous
556 studies and demonstrate that PM can promote the expansion of pre-existing mutant cells via
557 an inflammatory axis with no detectable environmental carcinogenic DNA signature, which
558 may be amenable to targeting to limit the risk of tumour promotion.

559

560 Extending previous findings establishing associations between air pollution and lung
561 cancer^{30,31}, including LCINS²⁹, we found an association between the frequency of EGFRm
562 lung cancer incidence and rising PM_{2.5} levels in cohorts from England, South Korea, Taiwan
563 and Canada. Moreover, temporal analysis of the Canadian cohort and UKBB suggests that 3
564 years of PM_{2.5} may be sufficient to increase risk of EGFRm lung cancer relationship.

565

566 A limitation of our analysis of the relationship between EGFRm lung cancer and PM_{2.5} is its
567 ecological nature: using aggregate data instead of participant-level data. We also
568 acknowledge that variables associated with EGFRm status could confound our analysis
569 because they may not be fully adjusted for. In particular, in all three within-country cohorts,
570 and in agreement with the literature², EGFRm was more frequent amongst females, Asians,
571 and in lung adenocarcinoma cancer patients (Supplementary Tables 1-3). Even so, our lung
572 cancer study cohorts were well balanced for sex, covered geographically and genetically
573 distinct (Caucasian and Asian) populations, and our England analysis remained significant
574 when we restricted the cohort to adenocarcinoma (Extended Data Figure 1B). Moreover, the
575 functional animal models in this study are restricted to EGFRm and KRAS mutant lung
576 adenocarcinoma only.

577

578 Consistent with a model in which PM exposure may serve as the promoter for clonal
579 expansions of oncogenic mutations in normal tissues this model, we find driver mutations in
580 *EGFR* and *KRAS* in normal human lung tissue, adding to research identifying mutations
581 within a range of histologically normal tissues²²⁻²⁵. These *EGFR* and *KRAS* mutations are
582 found at similar frequencies in normal lung tissue from patients with an established diagnosis
583 of NSCLC and from patients who do not acquire NSCLC in their lifetime.

584

585 We observed that PM promotes lung cancer in mouse models and fosters an AT2 progenitor
586 cell state in *EGFR* mutant cells from mice which can be replicated by incubating naïve PBS
587 exposed AT2 cells with PM exposed macrophages. Prior work has shown that the cytokine

588 IL1 β can promote formation and growth of progenitor AT2 cells³⁷ and we find that blocking
589 IL1 β *in vivo* is sufficient to attenuate PM-mediated EGFR mutant lung adenocarcinoma.
590 Although these mouse models will develop adenomas in the absence of PM and likely do not
591 replicate the complex spectrum of mutations found in normal tissue of a healthy adult, they
592 provide controlled environments to allow insight into early tumourigenesis. These results
593 suggest that cells in normal tissue harbouring driver mutations are restrained from tumour
594 progression but PM exposure can promote inflammation and trigger a rare population of
595 'dormant' cells to adopt a progenitor cell state, expand and initiate tumourigenesis, as seen
596 by the association of anthracosis and elevated variant allele frequency (VAF) of *EGFR*
597 mutations in normal human lung tissue. The rarity of these mutations in normal tissue (we
598 estimate 1:600,000 cells), combined with the scarcity of the AT2 population and the
599 prolonged requirement for PM exposure in humans may begin to explain the relatively low
600 frequency of EGFRm lung cancer at the population level and the resilience of the lung at the
601 single cell level to cancer initiation.

602

603 Our results provide additional evidence that a major risk factor for cancer development is not
604 only the inevitable acquisition of driver mutations in normal epithelium but also mechanisms
605 (both intrinsic and extrinsic) that promote nascent mutant cell expansion and progenitor
606 activity. Assuming little can be done to prevent the inexorable acquisition of oncogenic
607 mutations in normal tissues with age, attention must be turned to addressing the
608 mechanistic, DNA mutation-independent, causes of environmental carcinogenesis.

609

610 Balmain and colleagues have demonstrated that most environmental carcinogens tested do
611 not induce a DNA mutagenic signature; broad approaches will be necessary to establish
612 how these carcinogens as well as potential hormonal, environmental and germline
613 influences might promote or restrict mutant clone expansions and contribute to tumour
614 promotion. TRACERx has revealed that 8% of LUADs in smokers have no detectable
615 smoking carcinogenic signature²⁶. Further work should investigate the possibility that

616 tobacco exposure might promote lung cancer through non-mutagenic mechanisms. E-
617 cigarettes should also be evaluated for their potential to generate inflammatory responses in
618 the lung necessary for the promotion step in the Berenblum model. Indeed there is an urgent
619 need for carcinogenic assays that effectively reflect the potential for tumour promotion
620 across different tissues and to understand tissue-specific inflammatory mediators of this
621 process.

622

623 Such efforts may guide novel screening paradigms in high-risk, under-served populations
624 and “molecularly targeted” cancer prevention approaches to inhibit cancer initiation. It is
625 notable that the antibody Canikumumab, against one such “promoter” target, IL1 β , induced
626 in both mouse and human following PM exposure has already been shown to reduce lung
627 cancer incidence in the cardiovascular prevention trial, CANTOS⁶⁰.

628

629 In conclusion, our data suggest a mechanistic and causative link between pollution and lung
630 cancer, first proposed by Doll and Hill in 1950⁶¹, providing a public health mandate to
631 urgently restrict particulate emissions in urban areas.

Figure 1: Exploring the association between cancer and air pollution. A) Study design. B-D) Scatter plots showing relationships between PM_{2.5} and estimated EGFR mutant lung cancer incidence (per 100,000 population) at the country level in England (B), Korea (C) and Taiwan (D). The blue line

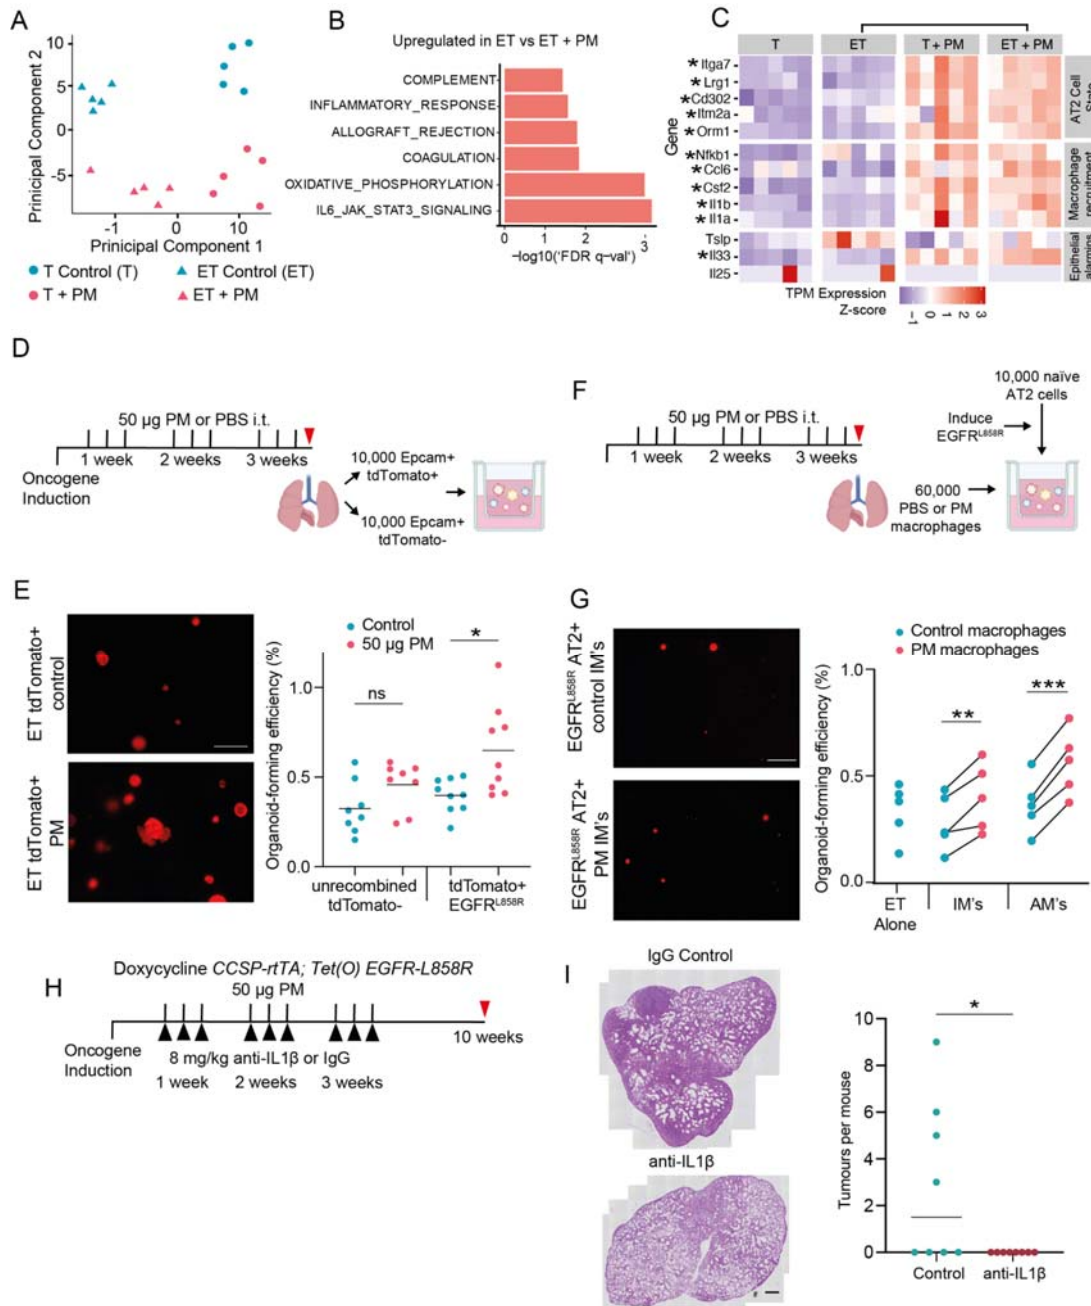

780 indicates the robust linear regression line. E) Forest plot indicating the relationship between cancer
781 risk and residential PM_{2.5} exposure levels (range: 8.17 - 21.31 µg/m³) in the UK Biobank dataset
782 (n=407,509). Each cancer type is displayed on a different row. Both raw p-values and FDR values are
783 provided. The color of the dots indicates the level of significance.

Figure 2: PM promotes lung tumorigenesis. A) Schematic of mouse model of lung cancer indicating induction of oncogene, followed by exposure (black lines) to particulate matter (PM) and tissue collection (red triangles). B) LEFT: Representative immunohistochemistry (IHC) of human EGFR^{L858R} in control and PM exposed ET mice. RIGHT: quantification of huEGFR^{L858R}

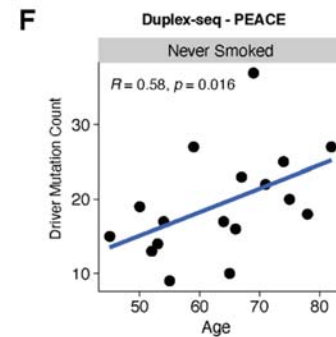

792 neoplasia/mm² of lung tissue (n=16 control & 5 µg group, n=15 for 50 µg group). C) Representative
793 diagram of spatially segmented clusters in control and PM exposed ET lungs at 10 weeks, lung lobe
794 outlined in grey and size of cluster colour is proportional to EGFR^{L858R} cluster size. Quantification of
795 average cluster size (D) and fraction of expanded clusters (>5 cells) (E) in PM and control mice at 3
796 and 10 weeks. F) LEFT: Quantification of lesions in control and PM exposed Rag^{-/-}; IL2rg^{-/-}
797 EGFR^{L858R} mutant mice at 10 weeks post induction and RIGHT: representative EGFR^{L858R} IHC. G)
798 Proportion of interstitial macrophages (IM's) and PDL1+ IM's within lung tissue determined by flow
799 cytometry in T and ET mice 24 hours after final control (blue) or PM (pink) exposure, (n=8 per group).
800 H) Representative histogram showing PD-L1 expression within lung interstitial macrophages in T(left
801 and ET (right) mice in control (blue) or PM-exposed (pink) conditions. I) LEFT: Representative
802 immunofluorescent images of CD68+ macrophages (cyan) and tdTomato+ EGFR mutant cells (red)
803 within ET lungs exposed to control or 50 µg PM either 3 weeks (left panel) or 10 weeks (right panel)
804 post oncogene induction. RIGHT: Quantification of CD68+ cells per mm² of lung tissue, selecting >30
805 random fields of view of 500 µm² (n= 4 mice per group). Gating strategies for flow cytometry analysis
806 provided in Extended Data Figure 6. Statistical analysis by one-way ANOVA for B, D, E, F, G & I.
807 Scale bars 100 µm (B,F,E), *p<0.05, **p<0.01, ***p<0.001, ****p<0.0001.

Figure 3: Elevated progenitor-like ability of EGFRm cells upon PM exposure. A) Principal component analysis plot of RNA-seq of epithelia from recombined T and E mice either exposed to PM or control. B) Significantly enriched GSEA pathways upregulated in ET-PM lung epithelial cells compared to ET control mice. C) Heatmap of progenitor AT2 cell state markers, inflammatory, and alarmin gene expression in all samples. The colour scale in the heatmap represents high (red) to low (blue) TPM expression z-scores; asterisks indicate significantly different gene expression between ET and ET + PM (black line). D) Schematic of epithelial organoid assay showing harvesting of lungs from mice exposed to PM or PBS followed by isolation and culture of epithelial (Epcam+) cells. E) LEFT: Representative fluorescent images of tdTomato organoids at day 14 from control ET mice or ET mice exposed to pollution in vivo and RIGHT: organoid forming efficiency (2 mice were pooled for each biological replicate for sufficient tdTomato+ cells: tdTomato- n=8 (16 mice); tdTomato+EGFR n=9 (18 mice)). F) Schematic of isolation of macrophages from mice exposed to PM or PBS and culture with naive (non-PM exposed) EGFR^{L858R} AT2 cells. G) LEFT: Representative fluorescent images of tdTomato AT2 derived organoids co-cultured with PM or PBS exposed macrophages and RIGHT:

825 quantification of organoid forming efficiency of EGFR mutant AT2 cells alone or with macrophages
826 compared to AT2 cells from the same mouse c-cultured with PM-exposed macrophages. H)
827 Schematic of anti-IL1 β treatment treatment (black triangles) during PM exposure (black lines) and
828 harvest (red triangle). I) LEFT: Representative H&E images of PM exposed mice treated with IgG
829 control antibody or anti-IL1B , RIGHT: quantification of tumours (n= 8 mice per group). Statistical
830 analysis by one-way ANOVA for F; paired-t test for G and Mann-Whitney for I. Scale bar 500 μ m (F, G

Figure 4: Mutational landscapes of normal lung tissue. A) Schematic indicating normal lung tissue cohorts analysed by ddPCR and Duplex-seq. B) The counts and proportions of PEACE and TRACERx normal lung samples that harbour *EGFR* mutations identified using ddPCR. The *EGFR* mutation type is indicated by the colour of the bars. C) The count and proportion of TRACERx normal lung samples (organised according to anthracotic pigment content) that harbour *EGFR* mutations identified by ddPCR. The *EGFR* mutation type is indicated by the colour of the bars. D) Beeswarm

842 plot indicating the variant allele frequencies of *EGFR* mutations, samples organized according to
843 presence (yes) or absence (no) of anthracotic pigment. Shapes of dots indicate smoking status. E)
844 Gene models of *KRAS* (top) and *EGFR* (bottom), where dots represent mutations identified in the
845 Duplex-seq-PEACE and Duplex-seq-BDRE cohorts. The position of the dots correspond to the loci of
846 the mutations while the height of the stack indicates the count of the number of mutations at a
847 particular protein coordinate. The shape of the dot indicates the diagnosis of the patient, while the
848 color of the dot indicates the mutation type. G) Scatter plot displaying correlation between age and
849 number of driver mutations identified in the never smoker samples (n=17) in the Duplex-seq PEACE
850 cohort, where the panel comprised genomic loci in 31 genes, including *EGFR* and *KRAS*.
851

852 Extended Data Figure Legends

853 Extended Data Figure 1: A) TX421 Tumours from Smokers. Barplots indicating proportion of
854 SNVs in each tumour attributed to each SBS mutational signatures. The barplots (Top:
855 LUAD, Bottom: LUSC) reflect the probability that clonal driver mutations in patients where
856 smoking-related signatures have been detected are caused by different mutational
857 processes (SBS4 and SBS92 smoking, SBS2 and SBS13 APOBEC, SBS1 and SBS5
858 aging). Each observed driver mutation in each patient is given a mutational-signature-
859 causing probability based on the trinucleotide context and the signatures exposure of the
860 patient (see methods), and then the probabilities are aggregated. Asterisks represent
861 patients where the smoking-related aggregated probabilities are below 0.5. B) Correlation
862 between PM2.5 levels and EGFRm Adenocarcinoma lung cancer incidence in England. C-D)
863 The Canadian Lung Cancer Cohort. C) Distribution of 3 year and 20 year cumulative PM2.5
864 exposure levels for all patients in the Canadian cohort. Red lines mark the thresholds that
865 were used to determine Low, Intermediate and High groups that are used in (D). These are
866 the 1st (6.77ug/m3) and 5th quintiles (7.27ug/m3) of the distribution. The full distribution is
867 displayed in the top plot, while the bottom plot displays a narrower range of 4-10 ug/m3 (for
868 clarity). D) Counts and frequencies of EGFRm in the Canadian Cohort, where 3 year and 20
869 year cumulative PM2.5 exposure levels were available. Patients are grouped into high,
870 intermediate and low groups based on thresholds established as described in (C). These
871 groups are defined based on 3 year cumulative PM2.5 exposure data (left) and based on 20
872 year cumulative PM2.5 exposure data (right). The bar plots display the counts and frequency
873 of EGFRm amongst patients within each group. The frequency of EGFRm is significantly
874 higher in the high pollution exposure group when compared to the low pollution exposure
875 group only based on 3 year cumulative PM2.5 exposure data but not based on 20 year
876 cumulative PM2.5 exposure data.

877
878 Extended Data Figure 2: A) Schematic of PM exposure and representative IHC of ET mice
879 induced with AT2-specific SPC-Cre exposed to PM or PBS control and quantification of
880 neoplastic lesions (n=14 PBS, n=11 PM) B) Schematic of PM exposure followed by induction
881 of EGFR and quantification of precancerous lesions/mm² of lung tissue (n=9 PBS; n=8 5µg;
882 n=11 50µg; p=0.0241). C) Schematic of PM exposure and representative H&E of a lung
883 adenocarcinoma in a 50 µg PM exposed, doxycycline treated *CCSP-rtTa; TetO-EGFR^{L858R}*
884 mice; quantification of number of adenocarcinomas per mouse below (n = 9 per group). D)
885 Schematic of PM exposure and representative IHC for red fluorescent protein (RFP, marks
886 tdTomato+ cells) in *Rosa26^{LSL-tdTomato/+}; Kras^{LSL-G12D/+}* mouse model in control or 50 µg PM
887 exposed conditions; quantification of number of hyperplastic lesions per mouse (n= 9
888 control, n=9 5 µg and n=12 50 µg). Scale bar 50 µm (C main, H), 20 µm (C insert), 100 µm A
889 & D.

890
891 Extended Data Figure 3: WGS analysis of tumours from mice exposed to air pollution (n=5)
892 and those exposed to PBS controls (n=5). A) Displays mutational profiles for each tumour
893 sample according to the mutation trinucleotide context. B) Barplots indicate the counts of
894 mutations in each sample, where bars are colored based on the base change. C) Boxplot
895 comparing the counts of mutations between tumours from pollution exposed mice (Pollution)
896 and tumours from PBS exposed mice (PBS), All mutations are summarised in one plot on

897 the left, and are then further divided based on the base change of the mutation. D)
898 Attribution of mutations in each tumour sample to each single base substitution (SBS)
899 mutation signature. The shading indicates the weight of the signature within each sample.
900 Majority of the weights have been assigned to aging related signatures (SBS40, SBS5,
901 SBS1).

902
903 Extended Data Figure 4: A) Immune cell frequencies in the lungs estimated by FACS 24
904 hours post-exposure from tdTomato (T) and EGFR mutant (ET) mice after 50µg (red) or
905 control (blue) (n=8 mice per group). Data are presented as the frequency among live
906 immune cells. Representative immunofluorescent images of CD68+ macrophages (cyan)
907 and tdTomato+ Kras mutant cells (red) within KT lungs (B) or *CCSP-rtTA; TetO EGFR^{L858R}*
908 lungs (C) exposed to control or 50 µg PM 10 weeks post oncogene induction and
909 quantification of CD68+ cells per mm² of lung tissue, selecting >20 random fields of view of
910 500 µm² (n= 3 mice per group). Scale bar 50 µm B & C, 150 µm D.

911
912 Extended Data Figure 5: A) Significantly enriched GSEA pathways upregulated in T-PM lung
913 epithelial cells compared to T control mice. B) Progenitor-like AT2 score based on
914 deconvolution of bulk RNA-seq of T and ET mice exposed to 50 µg PM or PBS. C)
915 Schematic displaying experimental set-up of clinical exposure study in never-smoker
916 volunteers initially reported in ³⁸, crossover design with (i) and (ii) in random order separated
917 by 4-week washout. D) Fold change (FC) of significantly upregulated genes (identified in
918 mouse) compared to the fold change of genes changed in the clinical exposure study. With
919 common directionality across species indicated (negative: grey background; positive: red
920 background). E) Schematic of AT2 culture from E or ET mice exposed to 50 µg PM or PBS.
921 F) Representative fluorescent images of tdTomato organoids at day 14 from E or ET mice
922 exposed to pollution in vivo. G) Quantification of AT2 organoid forming efficiency. n=4 mice
923 per group T and n=5 mice per group ET.H) Fluorescent imaging of Keratin8+ (magenta),
924 SPC+ (blue) AT2 organoids. I) Quantification of IL1B RNAscope and representative IHC. J)
925 Quantification of IL1β positive CD68+ cells at 3 weeks post induction in ET mice following
926 exposure to PM and representative image of IL1B RNAscope (green) in CD68 positive (red)
927 macrophages, arrows indicate positive macrophages. n=3 mice per group and error bar is
928 s.d K) Representative fluorescent images of EGFR-L858R+ AT2 organoids from ET mice
929 treated with control or IL1β in vitro. tdTomato (yellow) organoids stained with SPC (blue) and
930 Keratin 8 (magenta). Scale bar 100µm. Quantification of organoid size with each dot
931 representing an organoid at day 14 of control (blue) or IL1β treated (orange). n=3 mice per
932 group. Scale bar 100 µm F; 20 µm H, I; 50 µm J, K.

933
934 Extended Data Figure 6 Gating Strategy: A, B) Example of FACS gating strategy to
935 determine frequency of (A) alveolar macrophages, interstitial macrophages, neutrophils,
936 dendritic cells and (B) epithelial cells both tdTomato positive and negative. All samples were
937 gated to exclude debris and doublets, followed by live cell discrimination. C) Representative
938 picture from a tdTomato treated with PBS via i.t for 3 weeks using sort strategy for AT2 cells
939 defined in Major et al., 2020 and macrophages defined in Choi et al., 2020.

940
941 Extended Data Figure 7: CONSORT Diagrams for the normal lung tissue profiling cohorts
942

943 Extended Data Figure 8: A)TRACERx and PEACE Cohort for ddPCR of 5 EGFRm. (i)
944 Clinical information for each patient, (ii) Tumour EGFR mutation status, (iii) Normal EGFR

945 mutation status. B) Representative H & E images from anthracotic pigment identification in
946 TRACERx normal tissue. C) Comparing area of normal tissue harbouring anthracotic
947 pigment in never smokers and smokers. Each dot represents the ratio of pigmented area
948 respective to total tissue in each anthracosis positive normal lung tissue sample. D)
949 Regression analysis of characteristics influences EGFRm presence in normal lung tissue for
950 ddPCR-TRACERx cohort (n=195).

951

952 Extended Data Figure 9: A) Top: EGFR Mutations detected using Duplex-seq across EGFR
953 exons 18-21 on normal lung samples from the BDRE Study. Bottom: VAFs of each EGFR
954 mutation are displayed. B) Top: KRAS Mutations detected using Duplex-seq across KRAS
955 exons 2-3 on normal lung samples from the BDRE Study. Bottom: VAFs of each KRAS
956 mutation are displayed. A-B) Only cancer-related mutations annotated in the cancer gene
957 census are displayed. Mutations with strong evidence of being a lung cancer driver mutation
958 are indicated in red, while mutations with some evidence of being a lung cancer driver
959 mutation are indicated in pink, all other drivers annotated in COSMIC are indicated in blue.
960 C) VAFs of KRAS mutations across samples of different cancer types. The one patient who
961 received BRAF inhibitor treatment is indicated in purple. D) Comparing VAFs of high
962 confidence (var count ≥ 2 , strong evidence) driver mutations in EGFR and KRAS. TOP:
963 Box plots summarise VAFs across samples. Mutations are grouped according to the gene
964 harbouring the mutation and smoking status of the patient. BOTTOM: dot plots show VAFs
965 of mutations in each sample. Where a sample has 2 mutations, they are both indicated. Dots
966 are coloured by the gene harbouring the mutation (EGFR or KRAS) (Details of driver
967 mutations can be found in Supplementary Table S5)

968

969

970

971 Methods

972 1. Normal Tissue Profiling

973 1.1) ddPCR of samples from TRACERx and PEACE studies

974 Tumour and normal lung tissue samples

975 This project leverages the infrastructure established by the national pan-cancer research
976 autopsy programme (PEACE, NCT03004755) and the prospective, longitudinal cohort study
977 (TRACERx) of non-small cell lung cancer (NCT01888601)¹.

978
979 To explore whether clinical disparities in never smoker lung cancer were reflected in normal
980 lung tissue *EGFR* mutation status, we sought to assemble a cohort comprising TRACERx
981 patients that were as best as possible balanced for sex (males vs females), smoking status
982 (never smoker vs ever smoker) and *EGFR* mutation status in tumour samples (EGFRm vs
983 EGFRwt). To uncover if *EGFR* mutations were also found in normal lung tissue from patients
984 who never acquire a lung cancer diagnosis in their lifetimes, we also assembled a cohort of
985 PEACE patients.

986
987 Based on tissue that was available for study, our dataset consisted of 195 tumour and 195
988 normal lung tissues from 195 TRACERx patients, and 59 normal lung tissues from 19
989 PEACE patients (median 3 samples per patient (range 1 to 10)).

990
991 In TRACERx, tumour and normal lung tissue were obtained at surgery. Normal lung tissue
992 was collected distally from the primary tumour tissue (at least approximately 2cm apart). All
993 tissue was initially snap-frozen and then a portion fixed and made into a FFPE block. A H&E
994 section of each block was cut and stained and underwent pathology review. We use 'normal'
995 to refer to non-malignant lung tissue. DNA was extracted from both the normal and tumor
996 frozen tissue proximal to these sections. In PEACE, normal lung tissue was collected at
997 post-mortem tissue harvest from patients who never acquire lung cancer in their lifetimes.
998 Each piece of tissue collected was immediately bisected and one half snap frozen and the
999 other fixed and then made into a FFPE block. H and E section of each block was cut and
1000 stained and underwent pathology review. DNA was then extracted from an adjacent normal
1001 frozen tissue sample.

1002
1003 All aforementioned H and E slides from tissues have undergone central pathology review. In
1004 particular, to exclude the possibility of contamination with tumour cells, thoracic pathologists
1005 have confirmed that all normal lung tissue samples do not contain any indication of tumour
1006 tissue or morphologically-defined pre-invasive disease. Thoracic pathologists also identified
1007 anthracotic pigment and reflected this in a binary score for its presence. For anthracosis
1008 positive cases, the proportion of the tissue covered by anthracotic pigment is also noted.
1009

1010 EGFR mutation profiling in normal samples (with ddPCR)

1011 DNA was extracted from normal lung tissue samples as previously described¹. DNA
1012 concentration was measured using Qubit, and up to 3,000 ng of DNA was fragmented to
1013 approximately 1,500 bp using the Covaris E220 evolution Focused-ultrasonicator following
1014 the manufacturer's standard protocol. SAGAsafe assays² for 5 *EGFR* target variant alleles
1015 (*EGFR* L858R, *EGFR* Exon 19 del, *EGFR* S768I, *EGFR* L861Q and *EGFR* G719S) were
1016 employed (SAGA Diagnostics AB). SAGAsafe is a digital PCR-based ultra-sensitive
1017 mutation detection technology utilizing an alternative chemistry alongside a modified
1018 thermocycling program, such that the true positive variant allele signal is enriched during a
1019 linear phase, and signals for both the variant and the wild-type alleles are amplified during
1020 the exponential phase. The method effectively suppresses the false positive variant allele
1021 signal rising from the polymerase base misincorporation errors and DNA damage, making
1022 reliable detection of rare-event mutations possible to exceedingly low limits of detection. The
1023 assays were performed on the Bio-Rad QX200 Droplet Digital PCR System. At least 3
1024 positive droplets were required to call a sample positive. Using control experiments
1025 containing 265,000-381,000 copies of wild-type genome equivalents per test, the achievable
1026 limit of detection for the five *EGFR* SAGAsafe assays was determined to be at least 0.004%
1027 VAF. For each patient sample, 500ng of fragmented DNA (corresponding to ~150,000
1028 copies of genome equivalents) was analyzed per assay across 4 reaction wells, with positive
1029 and negative control samples included in every run.

1030 Calculation of copy number concentration of the variant and the wild-type alleles

$$C_{V_i} = \frac{-\ln(1 - \frac{P}{T})}{V_d} \times \frac{V_r}{V_i}$$

1031

1032

1033 C_{V_i} is the copy number concentration of the target (variant or wild-type allele) in the input DNA
1034 sample

1035 P is the number of positive droplets for the target

1036 T is the number of total droplets analyzed

1037 V_d is the volume a droplet (0.85×10^{-3} μ L)

1038 V_r is the total volume of a ddPCR reaction (20 μ L)

1039 V_i is the input volume per ddPCR reaction of the input DNA sample

1040

1041 Calculation of the variant allele frequency (VAF)

$$VAF = \frac{C_{V_i}^{variant}}{C_{V_i}^{variant} + C_{V_i}^{wild-type}} \times 100\%$$

1042

1043 Estimation of EGFRm rate

1044 We considered all 5 oncogenic EGFR mutations detected via ddPCR in all TRACERx and
1045 PEACE (253 samples in total). Using the Approximate Bayesian computation model, we
1046 simulated ddPCR results of oncogenic EGFR mutations, and inferred a mutation rate of
1047 $4.07e-7$ per mutation (confidence interval: $1.61e-7$ to $6.08e-7$). Considering this mutation
1048 rate, we estimated that the frequency of identifying 1 EGFRm (of any of the 5 mutation
1049 types) would be 1 in 2,035,000 (95% confidence interval: 1 in 805,000 to 1 in 3,040,000). If
1050 we take the average of the 2 limits of the confidence interval, we obtain an estimate of an
1051 EGFRm being present in 1 in 554500 cells (or around 1:600,000 cells).
1052

1053 EGFR mutation profiling in corresponding tumour tissue (with MiSeq)

1054 For each tumour region and matched germline, capture of a custom panel of genes
1055 (including the *EGFR* locus) was performed on 125ng DNA isolated from genomic libraries.
1056 The TruSeq Custom Amplicon Library Preparation method was used. Following cluster
1057 generation, samples were 100bp paired-end multiplex sequenced on the Illumina MiSeq at
1058 the GCLP lab at University College London, as described previously¹. The generated data
1059 were aligned to the reference human genome (hg19) achieving a median sequencing depth
1060 of 3555X (Range: 1069-13084). Mutations were called as previously described¹.
1061
1062

1063 1.2) DuplexSeq of samples from the PEACE and BDRE studies

1064 Normal lung tissue samples

1065 PEACE cohort samples are collected as described above. For DuplexSeq we obtained an
1066 additional normal lung tissue from 48 PEACE patients. Here, both lung cancer and other
1067 cancer type patients were profiled (lung cancer n=9; other cancer n=39)
1068

1069 All BDRE cohort patients were enrolled under Biomarker for Dysplastic Epithelium (BDRE)
1070 (NCT00900419). The cohort consisted of individuals recommended for CT scan based on
1071 age, smoking history or other indications. If a suspicious nodule was detected by CT scan, a
1072 navigational bronchoscopy was indicated. The nodule site was sampled for accurate
1073 diagnosis. For each patient, a brushing from a remote site in a contralateral lobe was also
1074 taken for research, as a representative sample of normal tissue and subsequently profiled
1075 for mutations using DuplexSeq. The absence of nodules or masses detected by chest CT
1076 scans was indicative of the non-tumor nature of these contralateral samples. Each
1077 procedure was performed under fluoroscopic guidance with the brush advanced from the
1078 sheath only after documentation that the working channel was in the peripheral airways.

1079 EGFR and KRAS mutation profiling (with DuplexSeq)

1080 Genomic DNA was extracted from brushings using Qiagen DNeasy Blood & Tissue kit
1081 according to manufacturer's instructions. Duplex libraries were prepared using a
1082 commercially available kit from TwinStrand Biosciences, Inc. (Seattle, WA, USA) (CKD-
1083 00042 panel 000323), starting with 250ng of input DNA. Custom probes were designed for

1084 targeted capture of EGFR exons 18, 19, 20 and 21, and KRAS exons 2 and 3, along with 29
1085 other cancer genes.

1086

1087 By independently capturing and sequencing the two strands of DNA for selected genomic
1088 regions, combined with the use of a common unique molecular identifier for both strands,
1089 DuplexSeq allows for the detection of rare mutations^{3,4} with a sensitivity of less than 1 in 10⁷.
1090 After shearing and capturing of gDNA spanning the panel, primers are ligated that allow the
1091 two strands of DNA for each segment to be uniquely labelled and matched with its opposing
1092 strand. These strands are then amplified and libraries were sequenced on the NovaSeq
1093 6000 Sequencing System (Illumina Inc. San Diego, CA, USA) and sequencing data were
1094 analyzed on the DNAnexus platform. Samples had an average number of 150,000,000 raw
1095 reads, yielding a mean on-target duplex depth of 4500. DuplexSeq reads were processed
1096 using an in-house pipeline adapted from Valentine et al⁵ and a bioinformatics pipeline
1097 provided by TwinStrand BioSciences. Using this, we were able to identify mutations that
1098 were present in both the involved and contralateral lung samples.

1099

1100 Data Availability

1101 The MiSeq from the TRACERx and PEACE studies generated, used or analysed during this
1102 study are not publicly available and restrictions apply to the availability of these data. Such
1103 MiSeq data are available through the Cancer Research UK & University College London
1104 Cancer Trials Centre (ctc.tracerx@ucl.ac.uk) for academic non-commercial research
1105 purposes upon reasonable request, and subject to review of a project proposal that will be
1106 evaluated by a TRACERx data access committee, entering into an appropriate data access
1107 agreement and subject to any applicable ethical approvals.

1108

1109 The DuplexSeq data for the BDRE study were generated using a larger panel of probes that
1110 covered ~50 kb of the genome, spanning hotspots frequently mutated in cancers. All of the
1111 data for the EGFR and KRAS regions queried are included in this manuscript. Data for the
1112 other regions are not publicly available and restrictions apply to the availability of these data.
1113 Such DuplexSeq data are available through Professor James DeGregori
1114 (James.Degregori@cuanschutz.edu) for academic non-commercial research purposes upon
1115 reasonable request, entering into an appropriate data access agreement and subject to any
1116 applicable ethical approvals.

1117

1118 2. Epidemiological Studies

1119 Study populations

1120 2.1) UK Biobank dataset

1121 Available Data

1122 The UK Biobank (UKBB) study comprises over 500,000 participants, aged between 37-73
1123 who were recruited between 2006-2010. Participants provide detailed information regarding
1124 a comprehensive set of lifestyle factors, in addition to physical measurements and biological
1125 samples. Particulate matter air pollution levels (in 2010) are estimated for addresses within
1126 400km of the Greater London monitoring area using a land-use regression model developed
1127 as part of the ESCAPE study⁶.

1128 Associations between PM_{2.5} and lung cancer incidence in the UKBB data have already been
1129 calculated and described in⁷.

1130 Imputing Missing Data

1131 We first excluded all participants who had any cancer diagnosis pre-recruitment, alongside
1132 those with missing particulate matter or genetic principal components data. Multiple
1133 imputation with chained equations⁸ was used to impute missing smoking status (categorised
1134 into “never”, “previous”, and “current”; <1% missing), passive smoking (weekly hours of
1135 home tobacco exposure; 10.0% missing), pack-years of smoking(15.4% missing), BMI (<1%
1136 missing), household income (dichotomised by >= £31,000 annually; 14.6% missing),
1137 educational attainment (split by degree/professional qualification status; 1.31% missing)
1138 values. In addition to these, imputation models also used the following variables to predict
1139 values for missing data: PM_{2.5}, age at baseline, sex, BMI, the first 15 genetic principal
1140 components (to account for ethnicity), alongside cancer outcome and duration of follow-up.
1141 We used predictive mean matching, logistic regression, and random forest for continuous,
1142 binary, and categorical variables, respectively, performing a maximum of 180 iterations for
1143 the generation of each imputed data set. This yielded 15 complete versions of the original
1144 dataset in which the missing values have been imputed. This data set comprised 407,509
1145 individuals and represented 27 cancer types. Each imputed dataset was independently used
1146 in the same analysis protocol.

1147 Cox Regression To Identify Associations Between PM_{2.5} & Cancer Incidence

1148 Participants were followed up from recruitment until either date of each cancer diagnosis
1149 (obtained through linkage to national cancer registries) or censoring, which was defined as
1150 time of death, lost to follow-up, or the end of 2018, whichever was earlier. We created a
1151 multivariate Cox regression model for each imputed dataset and primary cancer type with >=
1152 100 cases (excluding non-melanoma skin cancer, and cancers restricted to one sex), and
1153 pooled results across these models, which were consistent for each cancer type, into a
1154 single set using Rubin’s rules⁸. Confidence intervals were calculated using:
1155 $e^{estimate_{pooled}} \pm (1.96 * standard\ error_{pooled})$. These models included the same covariates as in
1156 the imputation model. For laryngeal alongside lip and oropharyngeal cancers, we further
1157 corrected for alcohol consumption, excluding those participants with missing alcohol data
1158 due to the high missingness of these variables (30.7%). Schoenfeld residuals were
1159 examined to assess the proportional hazards assumption, with non-proportionality confirmed
1160 using Kaplan-Meier curves for binary and categorical variables. Potential departures from
1161 the proportional hazards assumption were noted for anal (smoking status), bladder (genetic
1162 principal component 12), kidney (age and smoking status), and melanoma (genetic principal
1163 component 9 and sex). We note high median (across all 15 imputations) variance inflation
1164 factor values (VIF >= 5) for the following covariates: genetic principal component 1 (other

1165 and unspecified biliary tract parts), 2 (AML, follicular nodular NHL, larynx, mesothelioma,
1166 other and unspecified biliary tract parts, peripheral and cutaneous T lymphomas,
1167 retroperitoneum and peritoneum), and 3 (AML, follicular nodular NHL, larynx, mesothelioma,
1168 other and unspecified biliary tract parts, peripheral and cutaneous T lymphomas). Finally, we
1169 report FDR-corrected p-values for the PM_{2.5}-cancer incidence association, to account for
1170 multiple testing.

1171 Our methods differed from those of Huang et al., in the following ways:

- 1172 ● We made use of the more refined cancer registry data rather than hospital diagnosis
1173 data. In particular, some of the cancer type definitions for lung and renal cancers are
1174 refined and updated in Supplementary Table S1. We also changed the censoring
1175 date to the last day of 2018 instead of it being the date of last diagnosis of each
1176 cancer type.
- 1177 ● To enhance the robustness of our work:
 - 1178 ○ We excluded PM_{2.5-10} and PM₁₀ (due to collinearity) and participants with any
1179 cancer diagnosed pre-baseline
 - 1180 ○ Used age at baseline instead of age at diagnosis
 - 1181 ○ Included additional dependent variables (cancer diagnosis and time till end of
1182 follow-up) in imputation models
 - 1183 ○ Increased the number of imputations from 5 to 15 and iterations from 90 to
1184 180
 - 1185 ○ Augmented our multivariate analysis to better account for the effect of
1186 smoking by categorising participants into "never", "previous", and "current"
1187 smokers. We also controlled for the smoking intensity by including pack-years
1188 of smoking as a continuous variable in our regression models.

1189 Interaction test between PM_{2.5} and smoking

1190 An interaction test between PM_{2.5} and smoking was performed for lung cancer, considering
1191 only participants with complete covariate data in the multivariable Cox regression.

1192 LUAD-specific analysis

1193 We considered only participants with cancer registry histology entries that map to LUAD
1194 (Supplementary Table S1). Imputations and all downstream modelling was performed
1195 independently for this analysis.

1196 Analysis taking into account migration

1197 Since the PM_{2.5} data is available for each participant's address, we assume that participant
1198 PM_{2.5} exposures remain constant throughout the study period. To account for exposure
1199 miss-classification, we additionally performed a separate analysis including only participants
1200 who had lived at their current address for at least three years prior to baseline. All
1201 imputations and downstream analysis was performed independently for this subgroup.

1202 Association between radon exposure and lung cancer incidence

1203 Radon exposure data from PHE was merged with the UKBB dataset based on home
1204 location coordinates. Since the data from PHE had greater spatial resolution, values were

1205 aggregated by the mode radon potential class (breaking ties through taking the higher class
1206 value) across all PHE coordinate values that map to each rounded coordinate in the UKBB.
1207 Imputations and downstream analyses were performed as described above, using modal
1208 radon exposure instead of PM_{2.5}.

1209

1210 2.1.1 Comparison of UKBB Population with General UK Population

1211 We have provided a table (Supplementary Table S4) comparing some characteristics
1212 between the UKBB population we studied and UK population estimates for reference.
1213 Compared with the general population, UKBB participants consisted of fewer current
1214 smokers, were more highly educated, had lower household income, more likely to be female,
1215 older, White, and live in areas with lower PM_{2.5} levels.

1216 2.2) Within-country datasets

1217 2.2.1) England dataset (Public Health England)

1218 Air pollution, lung cancer incidence and EGFR mutation status could be estimated for 20
1219 cancer alliance regions in England. This was the geographical level at which all three factors
1220 could be quantified.

1221

1222 **Air pollution:** Annual PM_{2.5} air pollution data (µg/m³) from 2006 to 2017 was obtained at the
1223 grid code level (1km x 1km) from DEFRA⁹. Radon potential (defined as the estimated
1224 percentage of homes in an area above the radon action level) in 2011 was obtained from the
1225 British Geological Survey at the grid code code level (UK Health Security Agency (UKHSA)-
1226 British Geological Survey (BGS). Radon data: indicative atlas of radon in Great Britain.
1227 <https://www.bgs.ac.uk/datasets/radon-data-indicative-atlas-of-radon/>). Postal code coordinates
1228 were sourced from the ONS 2018 Postal Code Directory¹⁰. To link every postal code to a
1229 grid code with pollution data, the coordinates of every postal code centroid was mapped to
1230 those of the nearest grid code centroid using the RANN package in R. The postal codes with
1231 pollution data were binned into 1 of 20 Cancer Alliance regions. Then, PM_{2.5} concentration
1232 estimates were then aggregated to the Cancer Alliance region level and then averaged over
1233 the period 2008 to 2017 for 2018 diagnoses, 2007 to 2016 for 2017 diagnoses and 2006 to
1234 2018 for 2016 diagnoses - these were selected because they represented the 10 years prior
1235 to a lung cancer diagnosis. The air pollution levels in each Cancer Alliance region were
1236 broadly stable (within 5 µg/m³) in this time period.

1237

1238 **Lung cancer incidence:** Data on 118,019 (2016: 39,229, 2017: 39,500, 2018: 39,290) lung
1239 cancers (International Classification of Diseases codes C33 to C34) diagnosed in England
1240 between 1 January 2016 and 31 December 2018 were extracted from the National Cancer
1241 Registration Dataset (NCRD) [AV2018 in CASREF01 (end of year snapshot)], held by the
1242 National Disease Registration and Analysis Service at Public Health England. Lung cancer
1243 incidence for each Cancer Alliance region was calculated based on these cases. This
1244 represented a predominantly Caucasian cohort - White: 92.06%, Asian: 1.48%, Chinese:
1245 0.23%, Black: 1.05%, Mixed: 0.28%, Other: 0.94%, Unknown: 3.96%.

1246

1247 The age-standardised lung cancer incidence (using population counts obtained from the
1248 Office of National Statistics 2019 (2018 mid-year estimates)) was obtained according to each
1249 five-year age group and sex. Incidences were then combined across age and sex to yield a
1250 single value for each alliance region.

1251
1252 Lung cancer incidence = $(\sum(w_i * x_i / d_i) / \sum(w_i)) * 100000$
1253 w_i = European population standard
1254 d_i = Population Count
1255 x_i = Case Count

1256
1257 Standardised rates are standardised according to the 2013 European Standard Population.
1258 Confidence intervals for ASR point estimates were calculated using the Dobson method.

1259
1260 **EGFR mutation proportion:** For lung cancer diagnoses listed above, *EGFR* mutation
1261 statuses were extracted from the NCRD [AT_GENE_ENGLAND table in the CAS2210
1262 monthly snapshot], which includes data on somatic tests undertaken from 1st January 2016
1263 to 31st December 2019. Only cases with “Overall: TS” as “a:abnormal” and “b:normal” for
1264 EGFR were used in the calculation for EGFR mutation rate (n=25,567). The EGFR mutation
1265 rate was calculated for each Cancer Alliance region.

1266
1267 EGFR mutation rate = $\langle \# \text{ a:abnormal} \rangle / (\langle \# \text{ a:abnormal} \rangle + \langle \# \text{ b:normal} \rangle)$
1268

1269 2.2.2) South Korea dataset (Samsung Medical Center)

1270 Air pollution, lung cancer incidence and EGFR mutation status could be estimated for 16
1271 geographical regions in South Korea. This was the geographical level at which all three
1272 factors could be quantified.

1273
1274 **Air pollution:** PM_{2.5} air pollution data were obtained from Air Korea¹¹ for the years 2015 to
1275 2017 for 16 standard geographical regions across Korea. Within each of the geographical
1276 regions, we averaged PM_{2.5} levels across the 2-year period prior to the year of lung cancer
1277 diagnosis. PM_{2.5} levels between 2015 to 2017 were broadly stable. We were only able to
1278 include PM_{2.5} data for a 2-year period for 2017 and 2018 diagnoses, as air pollution data per
1279 Korean region was only available starting from 2015.

1280
1281 **Lung cancer incidence:** Lung cancer incidence data were obtained from the Korean
1282 National Cancer Center¹² for the years 2017 to 2018 for 16 geographical regions across
1283 Korea. Sex and smoking data were not available. Lung cancer incidence was obtained
1284 separately for each year and considered independently in Pearson correlations that are
1285 described below.

1286
1287 **EGFR mutation proportion:** Lung cancer EGFR mutation status was obtained from
1288 Samsung Medical Center lung cancer diagnoses for the years 2017 to 2018 for 16
1289 geographical regions across Korea (n=2563). EGFR mutation rate was calculated as above.

1290 2.2.3) Taiwan dataset (Chang Gung Medical Foundation)

1291 Air pollution, lung cancer incidence and EGFR mutation status could be estimated for 12
1292 standard geographical regions in Taiwan. This was the geographical level at which all three
1293 factors could be quantified.

1294

1295 **Air pollution:** Annual PM_{2.5} air pollution data was obtained for 12 standard geographical
1296 regions in Taiwan from the Environmental Protection Administration Executive Yuan R.O.C.
1297 (Taiwan)¹³. PM_{2.5} (µg/m³) concentration estimates were available for each county in Taiwan
1298 from 2006 to 2017. We averaged PM_{2.5} levels across the period (up to 10 years before a 2
1299 year washout period) prior to the year of lung cancer diagnosis. Eg. For a diagnosis in 2017,
1300 2006-2015 aggregated air pollution levels were used for analysis; while for a diagnosis in
1301 2011, 2006-2009 aggregated air pollution levels were used for analysis. A 2 year washout
1302 period was necessary to account for dramatic decreases in air pollution levels after 2013.

1303

1304 **Lung cancer incidence:** Institutional lung cancer incidence and *EGFR* mutation rates for
1305 each of 12 different counties in Taiwan were obtained from the Chang Gung Research
1306 Database for the years 2011-2017 (n=4599). Lung cancer incidence was obtained
1307 separately for each year and considered independently in Pearson correlations that are
1308 described below.

1309

1310 Institutional lung cancer incidence was estimated based on recorded lung cancer diagnoses
1311 in all of Chang Gung Medical Foundation hospitals (CGMH), and the age-standardized rates
1312 (ASR) per 100,000 were calculated using the world (WHO 2000) standard population of lung
1313 cancer incidence.

1314

1315 **EGFR mutation proportion:** *EGFR* mutation testing data were available for all of these
1316 cases. However, only 9 counties had at least 10 cases with EGFR mutation tested per year
1317 and comprised >5% of the total population, these were the counties that were retained for
1318 analysis. EGFR mutation rate was calculated as above.

1319

1320 Relationship between EGFRm lung cancer incidence and PM_{2.5}

1321 Analyses were performed separately for each of the 3 cohorts: England, South Korea, and
1322 Taiwan.

1323

1324 For each geographical region (eg. each country; the 20 cancer alliances in England), *EGFR*
1325 mutant lung cancer incidence was calculated by multiplying the total lung cancer incidence
1326 by the *EGFR* mutation rate (as reported as a proportion out of 1).

1327

1328 EGFRm lung cancer incidence = <lung cancer incidence>*<EGFR mutation rate>

1329

1330 EGFR mutant lung cancer incidence values were compared with mean PM_{2.5} values across
1331 geographical regions using:

1332

1. Pearson correlation tests

1333

2. Weighted Pearson correlation tests (to account for number of tested cases in each
1334 geographical region)

1335 3. Robust linear regression (to account for outliers)

1336 *Sensitivity analysis for England and Korea data sets*

1337

1338 In the England data set, there were 2 Cancer Alliance regions (South East London and
1339 Thames Valley) with sparse data due to data unavailability (<5% of lung tumours have any
1340 molecular testing data recorded (2016-2018)). To exclude the possibility of this confounding
1341 our analysis, we performed a sensitivity analysis, where we excluded data from these 2
1342 regions. Of note, the correlation between PM_{2.5} and EGFRm lung cancer incidence was still
1343 significant (R=0.55; p=0.019) after these exclusions.

1344

1345 Similarly, in the South Korea data set Jeju-do (2017) was excluded due to poor data
1346 availability. The correlation between PM_{2.5} and EGFRm lung cancer incidence was still
1347 significant (R=0.38; p=0.033) after this exclusion.

1348

1349 However, for the sake of completion, we have reported the full data sets (including these 2
1350 England regions and 1 South Korea region) in the main text.

1351

1352 2.3) Canada Data Set (BC Cancer Research Centre, 1353 Vancouver BC, Canada)

1354 This data set comprises 228 female lung cancer cases that have been reported in Myers et
1355 al 2021¹⁴. These cases were seen at the Thoracic Surgery Department of the Vancouver
1356 General Hospital or the BC Cancer Vancouver Cancer Center between November 15, 2017,
1357 and May 31, 2019, and were prospectively invited to take part in the study. Detailed
1358 residential histories from birth to cancer diagnosis for residences within Canada and
1359 previous residences outside of Canada (for foreign-born immigrants) were recorded. Street
1360 and city address or postal codes allow accurate linking of residential locations to satellite-
1361 derived PM_{2.5} exposure data that were available from 1996 onward. A personal PM 2.5
1362 cumulative exposure was individually calculated via a detailed residential history from birth to
1363 current address, and input into geographical information System mapping (GIS). By applying
1364 high resolution (10X10 km) concentration estimates of particulate matter <2.5um from
1365 satellite observations, chemical transport models and ground measurements to each
1366 individual's residential history, a cumulative exposure was estimated by taking into account
1367 the intensity and duration of exposure and summing over all residences. EGFR mutation
1368 status for each patient was obtained from each patients' hospital record.

1369 Defining pollution exposure groups

1370 Low, Intermediate, and High air pollution groups were defined by considering quintiles of the
1371 distribution of PM_{2.5} exposure levels across the whole data set (3 year cumulative pollution
1372 data and 20 year cumulative pollution data).

1373

1374 Thresholds

1375 Bottom quintile: 6.77ug/m³

1376 Top quintile: 7.27ug/m³

1377
1378 PM_{2.5} Low: PM_{2.5}<bottom quintile
1379 PM_{2.5} Intermediate: PM_{2.5}>bottom quintile & PM_{2.5}<top quintile
1380 PM_{2.5} High: PM_{2.5}>top quintile

1381 Comparing EGFRm frequencies

1382 EGFRm frequencies were compared between high and low pollution exposure groups using
1383 Chi-squared tests. 2 comparisons were performed:
1384 • High vs Low Pollution (based on 3yr data)
1385 • High vs Low Pollution (based on 20 yr data)

1386 3. Preclinical studies

1387 Animal Procedures

1388 Animals were housed in ventilated cages with unlimited access to food and water. All animal
1389 regulated procedures were approved by The Francis Crick Institute BRF Strategic Oversight
1390 Committee, incorporating the Animal Welfare and Ethical Review Body, conforming with UK
1391 Home Office guidelines and regulations under the Animals (Scientific Procedures) Act 1986
1392 including Amendment Regulations 2012.

1393
1394 *EGFR*-L858R [Tg(tet-O-*EGFR*:L858R)56Hev] mice were obtained from the National Cancer
1395 Institute Mouse Repository. Rosa26tTA and Rosa26-LSL-tdTomato mice were obtained from
1396 Jackson laboratory. Mice were backcrossed onto a C57Bl6/J background and further
1397 crossed to generate Rosa26^{LSL-tTa/LSL-tdTomato}/Tet(O)*EGFR*^{L858R} mice. Rosa26rtTa/TetO-
1398 *EGFR*^{L858R} and Rosa26^{LSL-tdTomato};LSL-*Kras*^{G12D} mice have been described previously^{15,16}.
1399 After weaning, the mice were genotyped (Transnetyx, Memphis, USA), and placed in groups
1400 of one to five animals in individually ventilated cages, with a 12-hour daylight cycle. Cre-
1401 mediated recombination was initiated by adenoviral CMV-Cre (Viral Vector Core, University
1402 of Iowa, USA) delivered via intratracheal intubation (2.5x10⁷ virus particles/50 µl) or by Ad5-
1403 SPC-Cre delivery (Viral Vector Core, University of Iowa, USA, donated by Dr. Anton Berns
1404 from the Netherlands Cancer Institute) delivered via intratracheal instillation (2.5x10⁸ virus
1405 particles/50 µl).

1406
1407 For exposure to fine particulate matter or control, SRM2786 from the National Institute of
1408 Standards and Technologies (NIST, obtained from Sigma Aldrich) was resuspended in
1409 sterile PBS using sonication and particle size distribution was confirmed using a dynamic
1410 light scattering analyser (Zetasizer, mean particle diameter 2.8 µm). SRM2786 has certified
1411 mass fraction values of both organic and inorganic constituents from multiple analytical
1412 techniques and represents fine PM from a modern urban environment (Schantz et al., 2016).
1413 Mice were briefly anesthetized using 5% isoflurane and intratracheal administration of 5 µg,
1414 50 µg or control PBS was performed.

1415

1416 Fluorescence-activated cell sorting analysis and cell sorting

1417 For flow cytometry analysis of immune cells, mouse lungs were minced into small pieces,
1418 incubated with collagenase (1 mg/ml; ThermoFisher) and DNase I (50 U/ml; Life
1419 Technologies) for 45 min at 37°C and filtered through 100 µm strainers (Falcon). Red blood
1420 cells were lysed for 5 min using ACK buffer (Life Technologies). Cells were stained with
1421 fixable viability dye eFluor870 (BD Horizon) for 30 min and blocked with CD16/32 antibody
1422 (Biolegend) for 10 min. Cells were then stained with antibodies for 30 min (see
1423 Supplementary Table S6). Intracellular staining was performed using the
1424 Fixation/Permeabilization kit (eBioscience) according to the manufacturer's instructions.
1425 Samples were resuspended in FACS buffer (2% fetal calf serum in PBS) and analysed using
1426 a BD Symphony flow cytometer. Data was analysed using FlowJo (Tree Star).

1427

1428 For flow cytometry sorting of epithelial and immune cells, minced lung tissue was digested
1429 with Liberase TM and TH (Roche Diagnostics) and DNase I (Merck Sigma-Aldrich) in HBSS
1430 for 30 min at 37 °C in a shaker at 180 r.p.m. Samples were passed through a 100 µm filter,
1431 centrifuged (300 x g, 5 min, 4 degrees and red blood cells lysed as above. Extracellular
1432 antibody staining was then performed followed by incubation in DAPI (Sigma Aldrich) to label
1433 dead cells. Sorting strategies are outlined in Extended Data 6B,C. Cell sorting was
1434 performed on Influx, Aria Fusion or Aria III machines (BD).

1435

1436 Immunohistochemistry

1437 Mouse lungs were fixed overnight in 10% formalin and embedded in paraffin blocks. Then
1438 4 µm tissue sections were cut, deparaffinized and rehydrated using standard methods.
1439 Antigen retrieval was performed using pH 6.0 Citrate Buffer and incubated with the following
1440 antibodies human EGFR L858R mutant specific (Cell Signaling: 3197, 43B2), anti-RFP
1441 (Rockland: 600-401-379), CD11b (ab133357) and CD68 (ab283654). Primary antibodies
1442 were detected either using biotinylated secondary antibodies, followed by HRP/DAB or with
1443 subsequent OPAL fluorescence secondary antibodies (Akoya) . A commercial kit was used
1444 to detect IL1b RNA transcripts by RNAscope (ACD Biotechne) following manufacturers
1445 instructions, and staining for CD68 protein was performed afterwards and detected using
1446 OPAL fluorescence following manufacturers protocols (Akoya). And probes visualised using
1447 fluorescence to detect IL1b RNA and CD68 protein simultaneously. Slides were imaged
1448 using a Leica Zeiss AxioScan.Z1 slide scanner.

1449

1450 Tumour grading was carried out by two board-certified veterinary pathologists. Tumour foci
1451 were quantified from cell coordinate data by clustering cell positions by density using the
1452 DBSCAN algorithm, implemented in Python with the scikit-learn library¹⁷. We chose an EPS
1453 value of 35 for DBSCAN clustering as this produced spatial clusters with excellent
1454 concordance to visual inspection of foci in the original histological images. To assess the
1455 fraction of clusters that had expanded, we reasoned that wild type cells may divide only once
1456 between 3 and 10 weeks, based on the low proliferation rate of alveolar epithelial cells (Desai et al.

1457 2014). Since there was an average cluster size of 2 EGFR mutant cells at 3 weeks, we defined clusters
1458 >5 cells at 10 weeks as 'expanded clusters' that grew above expected

1459 Whole Genome Sequencing (WGS)

1460 Lung tumours from control-treated mice (PBS) (n=5) and PM exposed mice(n=5) were
1461 collected at ethical endpoint. Individual lung tumours were dissected from lung lobes and
1462 snap frozen. Germline DNA was extracted from tail tissue. DNA was isolated and prepared
1463 for WGS, followed by sequencing on a NovaSeq (Illumina), to achieve target coverage of
1464 100X for PBS and PM exposed samples, and 30X for germline samples. Sequences from all
1465 20 samples were processed using the Nextflow (version 21.10.3) Sarek pipeline (nf-
1466 core/sarek v3.0). Briefly, sequences were aligned with BWA (0.7.17) to mm10, and
1467 mutations were called with Mutect2 (gatk4: 4.1.8.1). Only passed mutations that were
1468 uniquely present in each tumour were considered for analysis. Mutational signatures were
1469 called using the DeconstructSigs R package, restricting our analysis to the common single
1470 base substitution signatures: SBS1, SBS4, SBS5, SBS2, SBS13, SBS40, SBS92, SBS17a,
1471 SBS17b, SBS18.

1472 Driver mutation probability

1473 The list of driver mutations and the mutational signature exposures are obtained from the
1474 TRACERx 421 publication¹⁸. Only patients with detected smoking-related signatures are
1475 considered in the analysis (TRACERx 421). Each observed clonal driver mutation is given a
1476 probability to be caused by all active mutational signatures in the patient. This number is
1477 derived from multiplying the mutational signatures exposures to the 96-channel profile of each
1478 signature¹⁹. Then the value is normalised to 1, so that each driver mutation can be explained
1479 by a fraction of active mutational signatures. The probabilities are then aggregated, giving the
1480 overall contribution to driver mutations from each of the active mutational signatures. A patient
1481 is defined as non-carrier of a tobacco-related driver mutation if the probability of SBS4 and
1482 SBS92 (smoking-related signatures) is smaller than 0.5.
1483

1484 RNA-Sequencing (RNA-seq)

1485 Lung CD45- CD31- Ter119- EpCAM+ were sorted from control and PM exposed mice by
1486 flow cytometry. Total RNA was isolated using the miRNeasy Micro Kit (Qiagen), according to
1487 the manufacturer's instructions. Library generation was performed using the KAPA RNA
1488 HyperPrep with RiboErase (Roche), followed by sequencing on a HiSeq (Illumina), to
1489 achieve an average of 25 million reads per sample.
1490

1491 The RNA-seq pipeline of nf-core framework version 3.3 was launched with Nextflow version
1492 21.04.0 to analyse RNA sequencing data²⁰. Raw reads in fastq files were mapped to
1493 GRCm38 with associated ensemble transcript definitions using STAR version 2.7.6a²¹. BAM
1494 files were sorted with a chromosome coordinate using samtools version 1.12 . RSEM
1495 version 1.3.1 was used to calculate estimated read counts per gene and to quantify in a
1496 measure of transcripts per million (TPM)²².
1497

1498 Differential expression analysis was performed using the R platform version 4.0.3 package
1499 DESeq. filtering with the absolute value of log fold change more 1 and p-value less than
1500 0.05²³. The gene expression between treatment groups was further analysed for their
1501 pathway enrichments using Gene Set Enrichment Analysis (GSEA). Normalisation (using z-
1502 scores) of TPM scores across the dataset was performed prior to plotting heatmaps of gene
1503 expression.

1504
1505 The AT2-like score was derived using the method described by Young et al²⁴. Briefly, bulk
1506 RNA-seq data from mouse models, with or without an EGFR mutation and in the presence
1507 or absence of PM, were compared according to the degree to which they were similar to a
1508 signature of keratin8+ AT2 transitional stem cells derived from single cell RNAseq data from
1509 Strunz et al.²⁵. Gene expression within genes overlapping the human and mouse genomes
1510 was used as input, and the pseudoR2 value from the Young et al approach used as a
1511 continuous variable in a test between the different conditions.

1512

1513 Comparison of RNA-seq data from mice to never-smokers in 1514 COPA study

1515 RNA sequencing was applied to 18 samples of bronchial brushings from 9 never-smokers from
1516 the COPA study after exposure to filtered air and diesel exhaust. Salmon²⁶ was used to estimate
1517 transcript-level abundance from RNA-seq read data. Differential expression analysis was
1518 performed using DESeq2²⁷. The log two fold difference in gene expression was calculated
1519 between samples collected 24 hours after exposure to diesel exhaust and filtered air
1520 (control), on separate occasions but from the same participants. P-values were adjusted
1521 using the Benjamini-Hochberg method. The log two fold change of significantly differentially
1522 expressed genes between the tdTomato control and tdTomato PM-treated mice were
1523 compared to the log two fold change expression of the genes from COPA participants.

1524

1525 The limitation of this analysis is that the mouse and human RNA-seq datasets fundamentally
1526 differ:

- 1527 • Mouse data is acquired from total lung EpCAM+ cells, containing both airway and
1528 alveolar tissue, whilst the human data were obtained from bronchial brushings only,
1529 hence different cell types are represented in the data.
- 1530 • The pollution exposure between species differed; human participants were exposed
1531 to diesel exhaust for 2 hours, compared to 3 weeks of PM exposure for mice.
1532 Furthermore, the mice were kept in controlled environments, whereas a 4 week
1533 wash-out period between exposure to filtered air and diesel exhaust in human
1534 participants was required, where day-to-day particulate matter exposures and
1535 lifestyle differences could not be controlled.
- 1536 • Fold changes from the human data were obtained by pairwise comparisons from
1537 each individual, while since we did not have pairwise matched data from each
1538 mouse, the fold changes from the mouse data were derived based on aggregated
1539 (mean) values across each condition (ie. air pollution vs control).

1540 • As well, the RNA-seq was performed at 2 different sequencing centres, and target
1541 depths were different. The human data was sequenced with a target depth of 30M
1542 reads/sample, while the mouse data was sequenced with a target depth of 25M
1543 reads/sample.

1544 Organoid forming assays

1545
1546 Lung organoid co-culture assays have been previously described²⁸. Briefly, tdTomato+ lung
1547 epithelial cells (tdTomato+EpCAM+CD45- CD31- Ter119-) were isolated by fluorescence-
1548 activated cell sorting (FACS) from control or PM exposed ET mice acutely after 3 weeks of
1549 treatment and were resuspended in 3D organoid media consisting of DMEM/F12 with 10%
1550 FBS, 100 U ml⁻¹ penicillin-streptomycin, insulin/transferrin/selenium, L-glutamine (all
1551 GIBCO) and 1mM HEPES (in-house). 5,000-10,000 cells were mixed with a murine lung
1552 fibroblast cell line (MLg2908, ATCC, 1:5 ratio) and resuspended in growth factor reduced
1553 Matrigel (Corning) at a ratio of 1:1. 100 µl of this mixture was pipetted into a 24-well transwell
1554 insert with a 0.4 µm pore (Corning). After incubating for 30 min at 37 °C, 500 µl of organoid
1555 media was added to the lower chamber and media changed every other day. Bright-field and
1556 fluorescent images were acquired after 14 days using an EVOS microscope (Thermo Fisher
1557 Scientific) and quantified using FiJi (.2.0.0-rc-69/1.52r, ImageJ).

1558
1559 For *ex vivo* interleukin-1-beta treatment of lung alveolar type II (AT2) cells, single cell
1560 suspensions from ET mice lungs (without *in vivo* Cre induction) were subject to AT2 cell
1561 purification as previously described (MHC Class
1562 II+CD49^{low}EpCAM+CD45- CD31- Ter119-)²⁴. Purified AT2 cells were incubated *in vitro* with
1563 6×10^7 PFU/ml of Ad5-CMV-Cre in 100µL per 100,000 cells 3D organoid media for 1hr at
1564 37 C as detailed in³⁰. Cells were washed three times in PBS before plating as above, with
1565 20ng/mL IL-1b added to the organoid media in the lower chamber and changed every other
1566 day. TdTomato+ organoids were counted as above and the size analysed in FiJi. For
1567 wholemount staining of organoids, organoids were prepared according to previous
1568 methods³¹ and stained with anti-proSPC (Abcam, clone EPR19839) and anti-keratin 8
1569 (DSHB Iowa, clone TROMA-1). 3D confocal images were acquired upon an Olympus
1570 FV3000 and analysed in FiJi.

1571
1572 For assessment of AT2 organoid formation after PM exposure, AT2 cells were isolated from
1573 control or PM treated T and ET mice after 3 weeks, without *in vivo* Cre induction, followed by
1574 Cre infection as above and 10,000 cells plated in the organoid assay as described. For co-
1575 culture of AT2 cells and macrophages, non-induced ET mice were exposed to either PBS or
1576 PM, followed by collection at 3 weeks and isolation of both AT2 cells, interstitial and alveolar
1577 macrophages as detailed in Choi et al³², (sorting strategies defined in Extended Data Figure
1578 6C). AT2 cells from PBS-treated ET mice only were infected with Cre *ex vivo* as described
1579 as above, before 10,000 AT2 cells were either plated with fibroblasts only, or with a 1:6 ratio
1580 of PBS- or PM- treated macrophages as above, modified from Choi et al. tdTomato+
1581 organoids were quantified in all conditions.

1582

1583 Statistics and Reproducibility

1584 Preclinical statistical analyses were performed using Prism (v.9.1.1, GraphPad Software).
1585 Epidemiological and mutation/sequence data analysis was performed in R version 3.6.2.
1586 Graphic display was performed in Prism and illustrative figures created with Biorender.com.
1587 A Kolmogorov–Smirnov normality test was performed before any other statistical test. After,
1588 if any of the comparative groups failed normality (or the number too low to estimate
1589 normality), a nonparametric Mann–Whitney test was performed. When groups showed a
1590 normal distribution, an unpaired two-tailed *t*-test was performed. When groups showed a
1591 significant difference in the variance, we used a *t*-test with Welch’s correction. When
1592 assessing statistics of three or more groups, we performed one-way analysis of variance
1593 (ANOVA) or nonparametric Kruskal–Wallis test.

1594

1595 No data were excluded. No statistical methods were used to predetermine sample size in the
1596 mouse studies, and mice with matched sex and age were randomized into different
1597 treatment groups. All experiments were reliably reproduced. Specifically, all in vivo
1598 experiments, except for omics data (RNA-seq), were performed independently at least twice,
1599 with the total number of biological replicates (independent mice) indicated in the
1600 corresponding figure legends.

1601

1602 Code Availability

1603 Normal lung tissue processing, RNA-seq analysis and WGS analysis code available at:

Acknowledgements

1680 This research has been conducted using the UK Biobank Resource under application
1681 number [82693]. This work has been supported by the Mark Foundation ASPIRE I Award
1682 (Grant 21-029-ASP), Lung Cancer Research Foundation Grant on Disparities in Lung
1683 Cancer, Advanced Grant (PROTEUS, Grant Agreement no. 835297), CRUK EDD
1684 (EDDPMA-Nov21\100034), and Rosetrees Out-of-round Award (OoR2020\100009). E.L.L.
1685 receives funding from NovoNordisk Foundation (ID 16584), The Mark Foundation (Grant 21-
1686 029-ASP) and has been supported by Rosetrees. W.H is funded by an ERC Advanced Grant
1687 (PROTEUS, Grant Agreement no. 835297), CRUK EDD (EDDPMA-Nov21\100034), The
1688 Mark Foundation (Grant 21-029-ASP) and has been supported by Rosetrees. C.E.W. is
1689 supported by a RESPIRE4 fellowship from the European Respiratory Society and Marie-
1690 Sklodowska-Curie Actions. K.C. is supported by Research Unit of Intelligence Diagnosis and
1691 Treatment in Early Non-small Cell Lung Cancer, Chinese Academy of Medical Sciences
1692 (2021RU002), National Natural Science Foundation of China (No.82072566) and Peking
1693 University People's Hospital Research and Development Funds (RS2019-01). T.K. receives
1694 grant support from JSPS Overseas Research Fellowships Program (202060447). S.H.L is
1695 supported by the National Research Foundation of Korea (NRF) grant funded by the Korea
1696 government (MSIT) (No. 2020R1A2C3006535), the National Cancer Center Grant
1697 (NCC1911269-3), and a grant of the Korea Health Technology R&D Project through the
1698 Korea Health Industry Development Institute (KHIDI), funded by the Ministry of Health &
1699 Welfare, Republic of Korea (grant number : HR20C0025). N.M. is a Sir Henry Dale Fellow,
1700 jointly funded by the Wellcome Trust and the Royal Society (Grant Number 211179/Z/18/Z)
1701 and also receives funding from Cancer Research UK, Rosetrees and the NIHR BRC at
1702 University College London Hospitals and the CRUK University College London Experimental
1703 Cancer Medicine Centre. EJE is supported by the Blumenthal Fellowship from the Linda
1704 Crnic Institute for Down Syndrome. J.D., M.G., Y.E.M. D.T.M. and R.L.K receive funding
1705 from American Association for Cancer Research/Johnson&Johnson (18-90-52-DEGR), and
1706 J.D. is supported by the Courtenay C. and Lucy Patten Davis Endowed Chair in Lung
1707 Cancer Research. M.G., Y.E.M. D.T.M. and R.L.K. were supported by National Cancer
1708 Institute (NCI) RO1 CA219893. E.J.E. was supported by NCI Ruth L. Kirschstein National
1709 Research Service Award T32-CA190216. The work at the University of Colorado was also
1710 supported by NCI Cancer Center Support Grant P30CA046934. M.J.-H. has received
1711 funding from Cancer Research UK, National Institute for Health Research, Rosetrees Trust,
1712 UKI NETs and NIHR University College London Hospitals Biomedical Research Centre. C.S.
1713 is Royal Society Napier Research Professor. He is supported by the Francis Crick Institute,
1714 which receives its core funding from Cancer Research UK (FC001169), the UK Medical
1715 Research Council (FC001169), and the Wellcome Trust (FC001169). C.S. is funded by
1716 Cancer Research UK (TRACERx, PEACE and CRUK Cancer Immunotherapy Catalyst
1717 Network), Cancer Research UK Lung Cancer Centre of Excellence, the Rosetrees Trust,
1718 Butterfield and Stonegate Trusts, NovoNordisk Foundation (ID16584), Royal Society
1719 Research Professorships Enhancement Award (RP/EA/180007), the NIHR BRC at
1720 University College London Hospitals, the CRUK-UCL Centre, Experimental Cancer Medicine
1721 Centre and the Breast Cancer Research Foundation (BCRF). This research is supported by
1722 a Stand Up To Cancer-LUNGevity-American Lung Association Lung Cancer Interception
1723 Dream Team Translational Research Grant (SU2C-AACR-DT23-17). Stand Up To Cancer is
1724 a program of the Entertainment Industry Foundation. Research grants are administered by
1725 the American Association for Cancer Research, the Scientific Partner of SU2C. C.S. also
1726 receives funding from the European Research Council (ERC) under the European Union's
1727 Seventh Framework Programme (FP7/2007-2013) Consolidator Grant (FP7-THESEUS-
1728 617844), European Commission ITN (FP7-PloidyNet 607722), an ERC Advanced Grant
1729 (PROTEUS) from the European Research Council under the European Union's Horizon
1730 2020 research and innovation programme (835297) and Chromavision from the European

1731 Union's Horizon 2020 research and innovation programme (665233). This work was
1732 supported by the Francis Crick Institute, which receives its core funding from Cancer
1733 Research UK (grant no. FC001112), the UK Medical Research Council (grant no.
1734 FC001112), and the Wellcome Trust (grant no. FC001112) and the European Research
1735 Council (grant no. ERC CoG-H2020-725492).

1736
1737 We thank the PEACE clinical and admin team for their assistance in data curation: Scott
1738 Shepherd, Zayd Tippu, Ben Shum, Charlotte Lewis, Molly O'Flaherty, Analyn Lucanas,
1739 Eleanor Carlyle, Lucy Holt, Fiona Williams. We also thank nursing and biospecimen
1740 coordinators for their assistance in sample curation: Kim Edmonds, Lauren Grostate, Karla
1741 Lingard, Denise Kelly, Justine Korteweg, Lauren Terry, Jennifer Bianco, Aida Murra, Kayleigh
1742 Kelly, Kema Peat, Nikki Hunter. We thank Alvin Ho-Kwan Cheung for assistance in
1743 pathology review. We thank Johanna Asklin and Cecilia Forsberg for logistical and technical
1744 assistance, and the Chang Gung Memorial Hospital for providing Chang Gung Research
1745 Database (CGRD) data. We are also grateful for support from the Flow Cytometry Unit, the
1746 Experimental Histopathology Unit, the Advanced Light Microscopy Facility, the Advanced
1747 Sequencing Facility and the Biological Resources Unit, especially Nicholas Chisholm and
1748 Jay O'Brien. We thank Agnes Yuen, Ayman Azhar, Kevin Lau, Carley Schwartz, Andrew
1749 Lee, and Chris Rider for their logistical support for the human exposure study. We also thank
1750 Centre d'expertise et de services Génome Québec for their sequencing services and support

1755

1756 Author Contributions

1757 W.H. and E.L.L. jointly designed the project, performed the experiments analyses and wrote
1758 the manuscript. W.H. performed the mouse experiments, E.L.L. performed the bioinformatics
1759 and epidemiology analyses. C.E.W. performed the mouse experiments, helped to write the
1760 manuscript and curated the mutation literature. C.L. performed the human RNA-seq
1761 analyses and curated the pollution data. M. A. performed the UK Biobank analyses. K.C.
1762 assembled and analyzed the TRACERx cohort. F.-C.K. and M.-H.L. performed the Taiwan
1763 epidemiological analyses. F.M., E.J.E.J., C.T., M.G., Y.E.M., D.T.M., and R.L.K. generated
1764 and analyzed the Duplex-seq data. O.P. wrote the Duplex-seq bioinformatics pipeline and
1765 performed the mutational signature analyses. H.C. and S.-H.L. performed the Korea
1766 epidemiological analyses. F.V.M, J.B., A.M. and D.C. were involved in mouse data
1767 acquisition. F.S.R. was involved with organoid experiments. S.V., A.R. and C.N.-L. curated
1768 and performed DNA extractions on TRACERx and PEACE samples, T.K. helped to analyse
1769 patient clinical characteristics. D.M. and M.S. performed pathological assessments of human
1770 tissue samples. A.N., B.B. J.R.M.B. and C.M.R. performed mouse RNA-seq analyses.
1771 M.H.R., R.D.H and S.L. designed and generated data for the human crossover study. A.S.-
1772 B. And S.L.P. were involved in mouse pathology analyses. M.L., K.L., J.P., S.H., F.R.
1773 curated the PHE data set, R.M. curated the Canadian cohort, M.A.B. and C.B. wrote and
1774 ran the MiSeq pipeline. C.A., L.H.S., Y.C. and A.M.G. performed the ddPCR experiments.
1775 I.M., J.D., T.J., N.K. and E.G. provided supervision over mouse experiments. M.-J. F., M.H.,
1776 P.A. and N.M. guidance supervision over bioinformatics analyses. S.L., P.S., R.H., C.T.,
1777 C.D.B., A.H. and K.L. provided supervision over epidemiological analyses. C.C. provided

1778 supervision over human cross over study. J.D.G. designed the BDRE study and supervised
1779 the normal tissue profiling work. M.J.-H. designed PEACE and TRACERx study protocols
1780 and E.L.L. and M.J.-H. jointly supervised the study and collaborations. C.S. designed and
1781 supervised the study and helped to write the manuscript.
1782

1783 Competing Interests

1784 M.A.B. has consulted for Achilles Therapeutics. T.J. is a member of the Board of Directors of Amgen
1785 and Thermo Fisher Scientific, and a co-Founder of Dragonfly Therapeutics and T2 Biosystems. T.J.
1786 serves on the Scientific Advisory Board of Dragonfly Therapeutics, SQZ Biotech and Skyhawk
1787 Therapeutics. T.J. is also President of Break Through Cancer. M.J.-H. is a CRUK Career
1788 Establishment Awardee and has received funding from CRUK, IASLC International Lung Cancer
1789 Foundation, Lung Cancer Research Foundation, Rosetrees Trust, UKI NETs, NIHR, NIHR UCLH
1790 Biomedical Research Centre; has consulted and is a member of the Scientific Advisory Board and
1791 Steering Committee for Achilles Therapeutics; has received speaker honoraria from Astex
1792 Pharmaceuticals, and Oslo Cancer Clusters; and holds a patent to methods for lung cancer detection
1793 (PCT/US2017/028013). N.M. has stock options in and has consulted for Achilles Therapeutics and
1794 holds a European patent in determining HLA LOH (PCT/GB2018/052004), and is a co-inventor to a
1795 patent to identifying responders to cancer treatment (PCT/GB2018/051912). C.D.B. has partnerships
1796 with GRAIL, LLC, NHS Galleri Trial, IDMC, Mercy BioAnalytics, Lucid DX, Medial EarlySign. C.S.
1797 acknowledges grant support from Pfizer, AstraZeneca, Bristol Myers Squibb, Roche-Ventana,
1798 Boehringer-Ingelheim, Archer Dx Inc. (collaboration in minimal residual disease sequencing
1799 technologies) and Ono Pharmaceutical; is an AstraZeneca Advisory Board Member and Chief
1800 Investigator for the MeRmaid1 clinical trial; has consulted for Amgen, Pfizer, Novartis,
1801 GlaxoSmithKline, MSD, Bristol Myers Squibb, AstraZeneca, Illumina, Genentech, Roche-Ventana,
1802 GRAIL, Medicxi, Bicycle Therapeutics, Metabomed and the Sarah Cannon Research Institute; has
1803 stock options in Apogen Biotechnologies, Epic Bioscience and GRAIL; and has stock options and is
1804 co-founder of Achilles Therapeutics. C.S. holds patents relating to assay technology to detect tumour
1805 recurrence (PCT/GB2017/053289); to targeting neoantigens (PCT/EP2016/059401), identifying patent
1806 response to immune checkpoint blockade (PCT/EP2016/071471), determining HLA LOH
1807 (PCT/GB2018/052004), predicting survival rates of patients with cancer (PCT/GB2020/050221), to
1808 treating cancer by targeting Insertion/deletion mutations (PCT/GB2018/051893), identifying
1809 insertion/deletion mutation targets (PCT/GB2018/051892); methods for lung cancer detection
1810 (PCT/US2017/028013), identifying responders to cancer treatment (PCT/GB2018/051912); and a
1811 patent application to determine methods and systems for tumour monitoring (GB2114434.0).
