#### Abstract

The conjecturally perfect Kirillov-Reshetikhin (KR) crystals are known to be isomorphic as classical crystals to certain Demazure subcrystals of crystal graphs of irreducible highest weight modules over affine algebras. Under some assumptions we show that the classical isomorphism from the Demazure crystal to the KR crystal, sends zero arrows to zero arrows. This implies that the affine crystal structure on these KR crystals is unique.

Keywords: Quantum affine algebras; Crystal bases; Demazure crystals; Kirillov-Reshetikhin crystals

## 1. Introduction

The irreducible finite-dimensional modules over a quantized affine algebra $U_{q}^{\prime}(\mathfrak{g})$ were classified by Chari and Pressley [3,4] in terms of Drinfeld polynomials. We are interested in the subfamily of such modules which possess a global crystal basis. Kirillov-Reshetikhin (KR) modules are finite-dimensional $U_{q}^{\prime}(\mathfrak{g})$-modules $W^{r, s}$ that were introduced in [7,8]. It is expected that

[^0]each KR module has a crystal basis $B^{r, s}$, and that every irreducible finite-dimensional $U_{q}^{\prime}(\mathfrak{g})$ module with crystal basis, is a tensor product of the crystal bases of KR modules.

The KR modules $W^{r, s}$ are indexed by a Dynkin node $r$ of the classical subalgebra (that is, the distinguished simple Lie subalgebra) $\mathfrak{g}_{0}$ of $\mathfrak{g}$ and a positive integer $s$. In general the existence of $B^{r, s}$ remains an open question. For type $A_{n}^{(1)}$ the crystal $B^{r, s}$ is known to exist [18] and its combinatorial structure has been studied [24]. In many cases, the crystals $B^{1, s}$ and $B^{r, 1}$ for nonexceptional types are also known to exist and their combinatorics has been worked out in [ 16,18 ] and [ 9,14$]$, respectively.

Viewed as a $U_{q}\left(\mathfrak{g}_{0}\right)$-module by restriction, $W^{r, s}$ is generally reducible; its decomposition into $U_{q}\left(\mathfrak{g}_{0}\right)$-irreducibles was conjectured in [7,8]. This was verified by Chari [1] for the nontwisted cases.

Kashiwara [13] conjectured that as classical crystals, many of the KR crystals (the ones conjectured to be perfect in $[7,8]$ ) are isomorphic to certain Demazure subcrystals of affine highest weight crystals. Kashiwara's conjecture was confirmed by Fourier and Littelmann [5] in the untwisted cases and Naito and Sagaki [22] in the twisted cases.

In this paper we prove that the classical isomorphism from the Demazure crystals to KR crystals sends zero arrows to zero arrows (see Theorem 4.4). It is not an affine crystal isomorphism but becomes an isomorphism after tensoring with an appropriate affine highest weight crystal. This recovers some of the isomorphisms given by the Kyoto path model. We emphasize this is accomplished without the assumption of perfectness of the KR crystals. The automorphisms on the crystals that are used in the definition of the ground state path in the Kyoto path model, come from affine Dynkin diagram automorphisms which can be calculated using the factorization of a translation element in the extended affine Weyl group in our setting. For the proof of our results we require the assumptions of regularity of KR crystals, the existence and uniqueness of a certain special element $u$ in a KR crystal, and the existence of automorphisms on KR crystals coming from certain Dynkin automorphisms (see Assumption 1). We show that under these assumptions, the KR crystals admit a unique affine crystal structure (see Corollary 4.6), and we give an algorithm which shows that twofold tensor products of KR crystals are connected (see Corollary 6.1). We expect that Assumption 1 holds, that is, if the existence of the KR crystals were established these hypotheses could be removed.

In Section 2 we establish notation and review some results about the extended affine Weyl group. The definition of Demazure crystals and KR crystals is given in Section 3. Section 4 contains our main result stated in Theorem 4.4 showing that all zero arrows of the Demazure crystal are present in the KR crystal. In Section 5 we provide explicit sequences of lowering operators leading from the special element $u$ of a KR crystal to all classical highest weight elements of the KR crystal. The connectedness of tensor products of KR crystals and an application regarding the algorithmic calculation of the combinatorial $R$-matrix can be found in Section 6.

## 2. Notation and basics

### 2.1. Affine Kac-Moody algebras

Let $\mathfrak{g}$ be an affine Kac-Moody algebra with Cartan subalgebra $\mathfrak{h}$, Dynkin node set $I=$ $\{0,1, \ldots, n\}$, Cartan matrix $A=\left(a_{i j}\right)_{i, j \in I}$, realized by the set of linearly independent simple roots $\left\{\alpha_{i} \mid i \in I\right\} \subset \mathfrak{h}^{*}$ and simple coroots $\left\{\alpha_{i}^{\vee} \mid i \in I\right\} \subset \mathfrak{h}$, such that $\left\langle\alpha_{i}^{\vee}, \alpha_{j}\right\rangle=a_{i j}$ [10]. Let $d \in \mathfrak{h}$ be the scaling element, which is any element such that $\left\langle d, \alpha_{i}\right\rangle=0$ for $i \in I \backslash\{0\}$ and $\left\langle d, \alpha_{0}\right\rangle=1$. Let $\left(a_{i} \mid i \in I\right)$ be the unique tuple of relatively prime positive integers that give
a linear dependence relation among the columns of $A$, and let $\left(a_{i}^{\vee} \mid i \in I\right)$ be the tuple for the rows of $A$. Let $\delta=\sum_{i \in I} a_{i} \alpha_{i}$ be the null root, $\theta=\sum_{i \in I \backslash\{0\}} a_{i} \alpha_{i}$, and $c=\sum_{i \in I} a_{i}^{\vee} \alpha_{i}^{\vee}$ the canonical central element. We have $\langle d, \delta\rangle=a_{0}$. Let $\left\{\Lambda_{i} \mid i \in I\right\} \subset \mathfrak{h}^{*}$ be the fundamental weights, which, together with $\delta / a_{0}$, are defined to the dual basis to the basis $\left\{\alpha_{i}^{\vee} \mid i \in I\right\} \cup\{d\}$ of $\mathfrak{h}$. In particular $\left\langle\alpha_{i}^{\vee}, \Lambda_{j}\right\rangle=\delta_{i j}$. Let $P=\bigoplus_{i \in I} \mathbb{Z} \Lambda_{i} \oplus \mathbb{Z}\left(\delta / a_{0}\right) \subset \mathfrak{h}^{*}$ be the weight lattice, $P^{+}=\bigoplus_{i \in I} \mathbb{Z} \geqslant 0 \Lambda_{i} \oplus \mathbb{Z}\left(\delta / a_{0}\right)=\left\{\lambda \in P \mid\left\langle\alpha_{i}^{\vee}, \lambda\right\rangle \geqslant 0\right.$ for all $\left.i \in I\right\}$ the set of dominant weights and $Q=\bigoplus_{i \in I} \mathbb{Z} \alpha_{i} \subset \mathfrak{h}^{*}$ the root lattice. The level of a weight $\lambda \in P$ is defined by $\langle c, \lambda\rangle$. Let $W$ be the affine Weyl group, generated by the simple reflections $\left\{s_{i} \mid i \in I\right\}$. $W$ acts on $P$ by $s_{i} \lambda=\lambda-\left\langle\alpha_{i}^{\vee}, \lambda\right\rangle \alpha_{i}$.

Let $(\cdot \mid \cdot)$ be the nondegenerate $W$-invariant symmetric form on $\mathfrak{h}^{*}$; it is defined by $\left(\alpha_{i} \mid \alpha_{j}\right)=$ $a_{i}^{\vee} a_{i}^{-1} a_{i j}$ for $i, j \in I,\left(\alpha_{i} \mid \Lambda_{0}\right)=0$ for $i \in I \backslash\{0\},\left(\alpha_{0} \mid \Lambda_{0}\right)=a_{0}^{-1}$, and $\left(\Lambda_{0} \mid \Lambda_{0}\right)=0$. One may check that [10, (6.4.1)]

$$
(\theta \mid \theta)=2 a_{0}= \begin{cases}4 & \text { for } A_{2 n}^{(2)}  \tag{2.1}\\ 2 & \text { otherwise }\end{cases}
$$

The pairing $(\cdot \mid \cdot)$ induces an isomorphism $v: \mathfrak{h} \rightarrow \mathfrak{h}^{*}$ given by $\left\langle v(h), h^{\prime}\right\rangle=\left(h \mid h^{\prime}\right)$ for all $h, h^{\prime} \in \mathfrak{h}$. So $\nu\left(\alpha_{i}^{\vee}\right)=a_{i}\left(a_{i}^{\vee}\right)^{-1} \alpha_{i}$ for $i \in I, \nu(d)=a_{0} \Lambda_{0}$, and $\nu(c)=\delta$. Define $\theta^{\vee} \in \mathfrak{h}$ by $\nu\left(\theta^{\vee}\right)=2 \theta /(\theta \mid \theta)=\theta / a_{0}$.

Let $\mathfrak{g}_{0} \subset \mathfrak{g}$ be the simple Lie subalgebra whose Dynkin node set is $I \backslash\{0\}$, with Weyl group $W_{0} \subset W$, root lattice $Q_{0}$, weight lattice $P_{0}$, and fundamental weights $\left\{\omega_{i} \mid i \in I \backslash\{0\}\right\} \subset P_{0}$.

Let $P^{\prime}=P / \mathbb{Z}\left(\delta / a_{0}\right)$. The natural projection $P^{\prime} \rightarrow P_{0}$ has a section $P_{0} \rightarrow P^{\prime}$ defined by $\omega_{i} \mapsto \Lambda_{i}-a_{i}^{\vee} \Lambda_{0}$ for $i \in I \backslash\{0\}$. The image of this section is the set of elements in $P^{\prime}$ of level zero.

### 2.2. Dynkin automorphisms

Let $X$ denote the affine Dynkin diagram and $\operatorname{Aut}(X)$ denote the group of automorphisms of $X$. By definition an element of $\operatorname{Aut}(X)$ is a permutation of the Dynkin node set $I$ which preserves the kind of bonds between nodes. Observe that

$$
\begin{align*}
& a_{\tau(i)}=a_{i}, \quad \text { for all } i \in I \text { and } \tau \in \operatorname{Aut}(X) .  \tag{2.2}\\
& a_{\tau(i)}^{\vee}=a_{i}^{\vee},
\end{align*}
$$

There is an action of $\operatorname{Aut}(X)$ on $P$ given by

$$
\begin{gathered}
\sigma\left(\Lambda_{i}\right)=\Lambda_{\sigma(i)}, \quad \text { for } i \in I, \\
\sigma(\delta)=\delta,
\end{gathered}
$$

for $\sigma \in \operatorname{Aut}(X)$. By (2.2) this action restricts to an action of $\operatorname{Aut}(X)$ on $P_{0}$ called the level zero action.

### 2.3. Translations

For $\alpha \in P_{0}$, define the element $t_{\alpha} \in \operatorname{Aut}(P)$ by [10, (6.5.2)]

$$
\begin{equation*}
t_{\alpha}(\lambda)=\lambda+\langle c, \lambda\rangle \alpha-\left((\lambda \mid \alpha)+\frac{1}{2}(\alpha \mid \alpha)\langle c, \lambda\rangle\right) \delta . \tag{2.3}
\end{equation*}
$$

The map $\alpha \mapsto t_{\alpha}$ defines an injective group homomorphism $P_{0} \rightarrow \operatorname{Aut}(P)$ whose image shall be denoted $T\left(P_{0}\right)$. For any $w \in W_{0}$,

$$
\begin{equation*}
w t_{\alpha} w^{-1}=t_{w(\alpha)} . \tag{2.4}
\end{equation*}
$$

Therefore, $W_{0} \ltimes T\left(P_{0}\right)$ acts on $P$. There is an induced action of $W_{0} \ltimes T\left(P_{0}\right)$ on $P^{\prime}$ that preserves the level of a weight. For every $m \in \mathbb{Z}$ there is an action of $W_{0} \ltimes T\left(P_{0}\right)$ on $P_{0}$ called the level $m$ action, given by $w *_{m} \mu=w\left(m \Lambda_{0}+\mu\right)-m \Lambda_{0}$ for $\mu \in P_{0}$. Under the level one action, the element $t_{\alpha}$ is precisely translation by $\alpha$.

### 2.4. Extended affine Weyl group

For each $i \in I \backslash\{0\}$, define $c_{i}=\max \left(1, a_{i} / a_{i}^{\vee}\right)$; these constants were introduced in [7]. Using the Kac indexing of the affine Dynkin diagrams [10, Table Fin, Aff1 and Aff2], we have $c_{i}=1$ except for $c_{i}=2$ for $\mathfrak{g}=B_{n}^{(1)}$ and $i=n, \mathfrak{g}=C_{n}^{(1)}$ and $1 \leqslant i \leqslant n-1, \mathfrak{g}=F_{4}^{(1)}$ and $i=3,4$, and $c_{2}=3$ for $\mathfrak{g}=G_{2}^{(1)}$. Consider the sublattices of $P_{0}$ given by

$$
\begin{gathered}
M=\bigoplus_{i \in I \backslash\{0\}} \mathbb{Z} c_{i} \alpha_{i}=\mathbb{Z} W_{0} \cdot \theta / a_{0}, \\
\tilde{M}=\bigoplus_{i \in I \backslash\{0\}} \mathbb{Z} c_{i} \omega_{i} .
\end{gathered}
$$

It is easy to check that $M \subset \widetilde{M}$ and that the action of $W_{0}$ on $P_{0}$ restricts to actions on $M$ and $\widetilde{M}$. Let $T(\widetilde{M})$ (respectively $T(M)$ ) be the subgroup of $T\left(P_{0}\right)$ generated by $t_{\lambda}$ for $\lambda \in \widetilde{M}$ (respectively $\lambda \in M)$.

There is an isomorphism [10, Proposition 6.5]

$$
\begin{equation*}
W \cong W_{0} \ltimes T(M) \tag{2.5}
\end{equation*}
$$

as subgroups of $\operatorname{Aut}(P)$. Under this isomorphism we have

$$
\begin{equation*}
s_{0}=t_{\theta / a_{0}} s_{\theta} \tag{2.6}
\end{equation*}
$$

Define the extended affine Weyl group to be the subgroup of $\operatorname{Aut}(P)$ given by

$$
\begin{equation*}
\widetilde{W}=W_{0} \ltimes T(\tilde{M}) . \tag{2.7}
\end{equation*}
$$

When $\mathfrak{g}$ is of untwisted type, $M \cong Q^{\vee}, \tilde{M} \cong P^{\vee}, c_{i} \omega_{i}=\nu\left(\omega_{i}^{\vee}\right)$, and $c_{i} \alpha_{i}=\nu\left(\alpha_{i}^{\vee}\right)$ for $i \in I \backslash\{0\}$.
Let $C \subset P \otimes_{\mathbb{Z}} \mathbb{R}$ be the fundamental chamber, the set of elements $\lambda$ such that $\left\langle\alpha_{i}^{\vee}, \lambda\right\rangle \geqslant 0$ for all $i \in I$. Define the subgroup $\Sigma \subset \widetilde{W}$ to be the set of elements that send $C$ into itself.

It follows from (2.4) and (2.5) that $W$ is a normal subgroup of $\widetilde{W}$. Thus $\Sigma$ acts on $W$ by conjugation. Since the Weyl chambers adjacent to $C$ are precisely those of the form $s_{i}(C)$ for $i \in I$, the element $\tau \in \Sigma$ induces a permutation (also denoted $\tau$ ) of the set $I$ given by

$$
\begin{equation*}
\tau s_{i} \tau^{-1}=s_{\tau(i)} \quad \text { for } i \in I . \tag{2.8}
\end{equation*}
$$

Since the braid relations in $W$ are preserved, $\Sigma$ is a subgroup of $\operatorname{Aut}(X)$.

### 2.5. Special automorphisms

We identify the subgroup $\Sigma$ explicitly. Say that an affine Dynkin node $i \in I$ is special if there is an automorphism $\tau \in \operatorname{Aut}(X)$ of the affine Dynkin diagram such that $\tau(i)=0$. In the untwisted case, $i$ is special if and only if $\omega_{i}^{\vee}$ is a minuscule coweight. Let $I^{0} \subset I$ denote the set of special vertices. Explicitly, using the Kac labeling [10]:

$$
I^{0}= \begin{cases}\{0,1, \ldots, n\} & \text { for } A_{n}^{(1)}, \\ \{0,1\} & \text { for } B_{n}^{(1)}, A_{2 n-1}^{(2)} \\ \{0, n\} & \text { for } C_{n}^{(1)}, D_{n+1}^{(2)}, \\ \{0,1, n-1, n\} & \text { for } D_{n}^{(1)}, \\ \{0,1,5\} & \text { for } E_{6}^{(1)}, \\ \{0,6\} & \text { for } E_{7}^{(1)}, \\ \{0\} & \text { otherwise }\end{cases}
$$

Proposition 2.1. For each $i \in I^{0}$ there is a unique element $\tau_{i} \in \Sigma$ such that $\tau_{i}(i)=0$. Moreover, $\Sigma=\left\{\tau_{i} \mid i \in I^{0}\right\}$.

We call $\tau_{i}$ the special automorphism associated with $i \in I^{0}$.
Note that every Dynkin automorphism is determined by its action on $I^{0}$. We describe the special automorphisms explicitly. $\tau_{0}$ is the identity automorphism. If $\mathfrak{g}$ is of untwisted affine type and $i \in I^{0}$ then for all $j \in I^{0}, \tau_{i}(j)=k \in I^{0}$ where $-\omega_{i}+\omega_{j} \cong \omega_{k} \bmod Q_{0}$ and $\omega_{0}=0$ by convention. For $\mathfrak{g}$ of twisted type the only nonidentity (special) automorphisms are the elements of $\operatorname{Aut}(X)$ which on $I^{0}$ are given by $\tau_{1}=(0,1)$ in type $A_{2 n-1}^{(2)}$ and $\tau_{n}=(0, n)$ in type $D_{n+1}^{(2)}$.

We now specify $\Sigma$ explicitly as a subgroup of permutations of $I^{0}$. In all cases but $D_{n}^{(1)}$ and $n$ even, $\Sigma$ is a cyclic group. This determines $\tau_{i}$ and $\Sigma$ completely except for types $A_{n}^{(1)}$ and $D_{n}^{(1)}$. For $A_{n}^{(1)}, \Sigma \cong \mathbb{Z} /(n+1) \mathbb{Z}$ where $\tau_{i}(j)=j-i \bmod (n+1)$ for all $i, j \in I^{0}$. For $D_{n}^{(1)}$ and $n$ odd, $\Sigma$ is cyclic with $\tau_{n-1}=(0, n, 1, n-1), \tau_{1}=(0,1)(n-1, n)$ and $\tau_{n}=(0, n-1,1, n)$ in cycle notation acting on $I^{0}$. For $n$ even, $\Sigma \cong \mathbb{Z} / 2 \mathbb{Z} \times \mathbb{Z} / 2 \mathbb{Z}$ with $\tau_{1}=(0,1)(n-1, n), \tau_{n-1}=$ $(0, n-1)(1, n)$ and $\tau_{n}=(0, n)(1, n-1)$.

Proposition 2.2. $\Sigma \cong \tilde{M} / M$ via $\tau_{i} \mapsto \omega_{i}+M$ for $i \in I^{0}$ and

$$
\begin{equation*}
\widetilde{W} \cong W \rtimes \Sigma \tag{2.9}
\end{equation*}
$$

as subgroups of $\operatorname{Aut}\left(P_{0}\right)$.
If $i \in I^{0}$ then $c_{i}=1$ and we have

$$
\begin{equation*}
\tau_{i}=w_{0}^{\omega_{i}} t_{-\omega_{i}} \tag{2.10}
\end{equation*}
$$

where, for $\lambda \in P_{0}^{+}$,

$$
\begin{equation*}
w_{0}^{\lambda} \in W_{0} \quad \text { is the shortest element such that } w_{0}^{\lambda} \lambda \text { is antidominant. } \tag{2.11}
\end{equation*}
$$

### 2.6. Dynkin automorphisms revisited

Let $X_{0}$ be the Dynkin diagram for the classical subalgebra $\mathfrak{g}_{0}$ of $\mathfrak{g}$.
Lemma 2.3. There is a group homomorphism

$$
\begin{align*}
\operatorname{Aut}(X) & \rightarrow \operatorname{Aut}\left(X_{0}\right), \\
\sigma & \mapsto \sigma^{\prime} \tag{2.12}
\end{align*}
$$

where $\sigma^{\prime}(i)=j$ if and only if $\sigma\left(\omega_{i}\right) \in W_{0} \omega_{j}$.
Proof. We first claim that there is a group action of $\operatorname{Aut}(X)$ on $W_{0} \backslash P_{0}$ defined by $\sigma\left(W_{0} \lambda\right)=$ $W_{0} \sigma \lambda$ where $\operatorname{Aut}(X)$ acts on $P_{0}$ via the level zero action. The level zero action of $s_{0}$ on $P_{0}$ is the same as that of $s_{\theta} \in W_{0}$, by (2.6) and (2.3). Thus for the level zero action, $W \lambda=W_{0} \lambda$ for $\lambda \in P_{0}$. By (2.8), $\sigma W_{0} \sigma^{-1} \subset W$ as it is generated by $s_{\sigma(i)}$ for $i \in I \backslash\{0\}$. Thus we have $W_{0} \sigma W_{0} \tau \lambda=W_{0}\left(\sigma W_{0} \sigma^{-1}\right) \sigma \tau \lambda=W_{0} \sigma \tau \lambda$. Therefore, $\operatorname{Aut}(X)$ acts on $W_{0} \backslash P_{0}$.

Next we show that this action restricts to an action on $F \subset W_{0} \backslash P_{0}$ where $F$ is the set of $W_{0}$-orbits of fundamental weights $\omega_{i}$ for $i \in I \backslash\{0\}$. Due to the above group action we need only that $\sigma F \subset F$ for generators $\sigma$ of $\operatorname{Aut}(X)$. By (2.2) we have $\sigma\left(\omega_{r}\right)=\omega_{\sigma(r)}-a_{r}^{\vee} \omega_{\sigma(0)}$ where we write $\omega_{i}=\Lambda_{i}-a_{i}^{\vee} \Lambda_{0}$ for all $i \in I$. Using this one may straightforwardly check the lemma for each affine root system.

Aut $\left(X_{0}\right)$ is trivial except in the following cases, where the homomorphism is described explicitly. The elements of $\operatorname{Aut}(X)$ and $\operatorname{Aut}\left(X_{0}\right)$ are given by their action as permutations of $I^{0}$ and $I^{0} \backslash\{0\}$, respectively.
(1) $\operatorname{Aut}\left(A_{n}\right)$ is generated by the involution $i \mapsto n+1-i$ for $i \in I \backslash\{0\}$. In this case $\operatorname{Aut}\left(A_{n}^{(1)}\right)$ is the dihedral group $D_{2(n+1)}$. For $\sigma \in \operatorname{Aut}\left(A_{n}^{(1)}\right), \sigma^{\prime}$ is the nontrivial element in $\operatorname{Aut}\left(A_{n}\right)$ if and only if $\sigma$ reverses orientation.
(2) $\operatorname{Aut}\left(D_{n}\right)$ is generated by $(n-1, n)$ when $n>4$. In this case $\operatorname{Aut}\left(D_{n}^{(1)}\right)$ is generated by $(0,1)$, $(n-1, n)$ and $(0, n)(1, n-1)$. All these map to the nontrivial element of $\operatorname{Aut}\left(D_{n}\right)$ except in the case that $n$ is even, when $(0, n)(1, n-1)$ maps to the identity.
(3) $\operatorname{Aut}\left(D_{4}\right)$ is the symmetric group on the three "satellite" vertices $\{1,3,4\}$. $\operatorname{Aut}\left(D_{4}^{(1)}\right)$ is the symmetric group on the vertices $\{0,1,3,4\}$ and is generated by $(0, i)$ for $i \in\{1,3,4\}$. The generator $(0, i)$ is sent to the element $(j, k)$ in $\operatorname{Aut}\left(D_{4}\right)$ where $\{0, i, j, k\}=\{0,1,3,4\}$ as sets.
(4) $\operatorname{Aut}\left(E_{6}\right)$ is generated by $(1,5) . \operatorname{Aut}\left(E_{6}^{(1)}\right)$ is isomorphic to the $S_{3}$ that permutes the special vertices $\{0,1,5\}$. Then each of the elements of order two in $\operatorname{Aut}\left(E_{6}^{(1)}\right)$ is sent to the nontrivial element of $\operatorname{Aut}\left(E_{6}\right)$.

Remark 1. In all cases, for all $\tau \in \Sigma, \tau^{\prime}$ is the identity in $\operatorname{Aut}\left(X_{0}\right)$. However for $\sigma=(0,1) \in$ $\operatorname{Aut}\left(D_{n}^{(1)}\right)$ we have $\sigma^{\prime}=(n-1, n) \in \operatorname{Aut}\left(D_{n}\right)$.

## 3. Crystals

### 3.1. Definition of crystals

A $P$-weighted $I$-crystal is a set $B$, equipped with Kashiwara operators $e_{i}, f_{i}: B \rightarrow B \sqcup\{\emptyset\}$, and weight function wt $: B \rightarrow P$ such that $e_{i}\left(f_{i}(b)\right)=b$ if $f_{i}(b) \neq \emptyset, f_{i}\left(e_{i}(b)\right)=b$ if $e_{i}(b) \neq \emptyset$, $\mathrm{wt}\left(f_{i}(b)\right)=\mathrm{wt}(b)-\alpha_{i}$ if $f_{i}(b) \neq \emptyset, \operatorname{wt}\left(e_{i}(b)\right)=\mathrm{wt}(b)+\alpha_{i}$ if $e_{i}(b) \neq \emptyset$, and $\left\langle\alpha_{i}^{\vee}, \mathrm{wt}(b)\right\rangle=$ $\varphi_{i}(b)-\varepsilon_{i}(b)$ where $\varphi_{i}(b)=\min \left\{m \mid f_{i}^{m}(b) \neq \emptyset\right\}$ and $\varepsilon_{i}(b)=\min \left\{m \mid e_{i}^{m}(b) \neq \emptyset\right\}$ are assumed to be finite for all $b \in B$ and $i \in I$. If $f_{i}(b) \neq \emptyset$ we draw an arrow colored $i$ from $b$ to $f_{i}(b)$. The connected components of the graph obtained by removing all arrows from $B$ except the arrows colored $i$, are called the $i$-strings of $B$. We write $\varepsilon(b)=\sum_{i \in I} \varepsilon_{i}(b) \Lambda_{i}$ and $\varphi(b)=\sum_{i \in I} \varphi_{i}(b) \Lambda_{i}$.

An $I$-crystal $B$ is regular if, for each subset $K \subset I$ with $|K|=2$, each $K$-component of $B$ is isomorphic to the crystal basis of an irreducible integrable highest weight $U_{q}^{\prime}\left(\mathfrak{g}_{K}\right)$-module where $\mathfrak{g}_{K}$ is the subalgebra of $\mathfrak{g}$ with simple roots $\alpha_{i}$ for $i \in K$.

The crystal reflection operator $S_{i}: B \rightarrow B$ is defined by the property that $S_{i}(b)$ is the unique element in the $i$-string of $b$ such that $\varepsilon_{i}\left(S_{i}(b)\right)=\varphi_{i}(b)$ or equivalently $\varphi_{i}\left(S_{i}(b)\right)=\varepsilon_{i}(b)$. This defines an action of the Weyl group $W$ on $B$ if $B$ is regular [12].

If $B$ and $B^{\prime}$ are $P$-weighted $I$-crystals, their tensor product $B \otimes B^{\prime}$ is a $P$-weighted $I$-crystal as follows (we use the opposite of Kashiwara's convention). As a set $B \otimes B^{\prime}$ is just the Cartesian product $B \times B^{\prime}$ where traditionally one writes $b \otimes b^{\prime}$ instead of $\left(b, b^{\prime}\right)$. The Kashiwara operators are given by

$$
\begin{aligned}
& f_{i}\left(b \otimes b^{\prime}\right)= \begin{cases}f_{i}(b) \otimes b^{\prime} & \text { if } \varepsilon_{i}(b) \geqslant \varphi_{i}\left(b^{\prime}\right), \\
b \otimes f_{i}\left(b^{\prime}\right) & \text { if } \varepsilon_{i}(b)<\varphi_{i}\left(b^{\prime}\right),\end{cases} \\
& e_{i}\left(b \otimes b^{\prime}\right)= \begin{cases}e_{i}(b) \otimes b^{\prime} & \text { if } \varepsilon_{i}(b)>\varphi_{i}\left(b^{\prime}\right) \\
b \otimes e_{i}\left(b^{\prime}\right) & \text { if } \varepsilon_{i}(b) \leqslant \varphi_{i}\left(b^{\prime}\right)\end{cases}
\end{aligned}
$$

Given any $P$-weighted $I$-crystal $B$ and Dynkin automorphism $\sigma$, there is a $P$-weighted $I$-crystal $B^{\sigma}$ whose vertex set is written $\left\{b^{\sigma} \mid b \in B\right\}$ and whose edges are given by $f_{i}(b)=b^{\prime}$ in $B$ if and only if $f_{\sigma(i)}\left(b^{\sigma}\right)=\left(b^{\prime}\right)^{\sigma}$. The weight function satisfies $\mathrm{wt}\left(b^{\sigma}\right)=\sigma(\mathrm{wt}(b))$ where the second $\sigma$ is the automorphism of $P$ defined by $\sigma$. A similar statement holds for $P_{0}$-weighted $I$-crystals, using the level zero action of $\sigma$ on $P_{0}$ defined in Section 2.2.

Given any $P$-weighted $I$-crystal $B$, define the contragradient dual crystal $B^{\vee}=\left\{b^{\vee} \mid b \in B\right\}$ with $\mathrm{wt}\left(b^{\vee}\right)=-\mathrm{wt}(b)$ and $f_{i}(b)=b^{\prime}$ if and only if $e_{i}\left(b^{\vee}\right)=b^{\wedge}$.

### 3.2. Branching

The following ideas have been applied extensively (in [18,25], for example) to identify the 0 -arrows in KR crystals. We shall use them here for the same purpose.

Let $B$ be the crystal graph of a $U_{q}^{\prime}(\mathfrak{g})$-module and $K \subset I$. A $K$-component of $B$ is a connected component of the graph obtained from $B$ by removing all $i$-edges for $i \notin K$. A $K$-highest weight vector is an element $b \in B$ such that $\varepsilon_{i}(b)=0$ for all $i \in K$. Suppose $K$ is a proper subset of $I$. Since the subalgebra of $\mathfrak{g}$ with simple roots $\left\{\alpha_{i} \mid i \in K\right\}$ is semisimple, each $K$-component of $B$ has a unique $K$-highest weight vector. When $K=I \backslash\{0\}$ we call the $K$-components and $K$-highest weight vectors classical components and highest weight vectors.

Suppose $\sigma$ is a Dynkin automorphism that fixes $K$ and induces an automorphism (also denoted $\sigma$ ) on $B$ that sends $i$-arrows to $\sigma(i)$-arrows for all $i \in I$. Then by definition $\sigma$ preserves
$i$-arrows for all $i \in K$. There is a projection from the classical weight lattice to that of the subalgebra with simple roots $\alpha_{i}$ for $i \in K$; we refer to the latter as the $K$-weight lattice. In particular $\sigma$ permutes the collection of $K$-components, sending $K$-highest weight vectors to those with the same $K$-weight (that is, $\varphi_{i} \circ \sigma=\varphi_{i}$ for $i \in K$ ).

### 3.3. Demazure modules and crystals

Let $\mathfrak{g}$ be a symmetrizable Kac-Moody algebra and $U_{q}(\mathfrak{g})$ its quantized universal enveloping algebra. For a dominant weight $\Lambda$ denote by $V(\Lambda)$ the irreducible integrable highest weight $U_{q}(\mathfrak{g})$-module with highest weight $\Lambda$. Write $B(\Lambda)$ for its crystal basis. Let $\mathfrak{b}$ be a Borel Lie subalgebra of $\mathfrak{g}$. For $\mu \in W \cdot \Lambda$ let $u_{\mu}$ be a generator of the line of weight $\mu$ in $V(\Lambda)$. Write $\mu=w \Lambda$ where $w$ is shortest in its coset $w W^{\Lambda}$ and $W^{\Lambda}=\{w \in W \mid w \Lambda=\Lambda\}$. When writing an element $w \Lambda \in W \cdot \Lambda$ we shall always assume $w$ is of minimum length. Define the Demazure module

$$
V_{w}(\Lambda):=U_{q}(\mathfrak{b}) \cdot u_{w(\Lambda)} .
$$

It is known that $V_{w}(\Lambda)$ has a crystal base $B_{w}(\Lambda)$ [11]; it is the full subgraph of $B(\Lambda)$ whose vertex set consists of the elements in $B(\Lambda)$ that are reachable by raising operators, from the unique element $u_{w \Lambda} \in B(\Lambda)$ of weight $w \Lambda$. We shall make use of the following result. By abuse of notation let

$$
\begin{equation*}
f_{w}(b)=\left\{f_{i_{N}}^{m_{N}} \cdots f_{i_{1}}^{m_{1}}(b) \mid m_{k} \in \mathbb{Z}_{\geqslant 0}\right\} \tag{3.1}
\end{equation*}
$$

where $w=s_{i_{N}} \cdots s_{i_{1}}$ is any fixed reduced decomposition of $w$. It is known [15,20,21] that as sets,

$$
\begin{equation*}
B_{w}(\Lambda)=f_{w}\left(u_{\Lambda}\right) \tag{3.2}
\end{equation*}
$$

For $\mathfrak{g}$ affine, let $w \in \widetilde{W}$. By (2.9) we may express it uniquely as $w=z \tau$ where $z \in W$ and $\tau \in \Sigma$. We define the Demazure module to be

$$
V_{w}(\Lambda):=V_{z}(\tau(\Lambda))
$$

Its crystal graph is denoted $B_{w}(\Lambda)=B_{z}(\tau \Lambda)$. For a dominant $\lambda \in \widetilde{M}$, let $\lambda^{*}=-w_{0}(\lambda)$, where $w_{0}$ is the longest element in $W_{0}$. Define $D(\lambda, s)=V_{t_{-\lambda^{*}}}\left(s \Lambda_{0}\right)$ and by abuse of notation, $D(\lambda, s)=B_{t_{-\lambda^{*}}}\left(s \Lambda_{0}\right)$. For any $\sigma \in \operatorname{Aut}(X)$ let $D^{\sigma}(\lambda, s)=B_{t_{-\sigma(\lambda) *}}\left(s \Lambda_{\sigma(0)}\right)$; it is obtained from $D(\lambda, s)$ by changing every $i$ arrow into a $\sigma(i)$ arrow.

### 3.4. KR crystals

Kirillov-Reshetikhin (KR) modules $W^{r, s}$, labeled by $(r, s) \in I \backslash\{0\} \times \mathbb{Z}_{>0}$, are finitedimensional $U_{q}^{\prime}(\mathfrak{g})$-modules. See [7] for the precise definition. It is conjectured that $W^{r, s}$ has a global crystal basis $B^{r, s}$.

In [7] a conjecture is given for the decomposition of each Kirillov-Reshetikhin (KR) module $W^{r, c_{r} s}$ into its $\mathfrak{g}_{0}$-components. Chari [1] proved this conjecture for the nonexceptional untwisted algebras and for the exceptional cases for the nodes $r$ such that either $r \in I^{0}$ or $\omega_{r}$ is the highest
root. Recently the $G_{2}$ case was treated in full [2]. In [5], the $\mathfrak{g}_{0}$-structure of the Demazure modules was calculated for the same cases as in [1], and it was verified that the Demazure and KR modules agree as $\mathfrak{g}_{0}$-modules. In addition, it was shown in [6] that no matter what the precise $\mathfrak{g}_{0}$-structure is, the Demazure and the KR modules agree as $\mathfrak{g}_{0}$-modules for all untwisted algebras. Naito and Sagaki [22] proved the conjectures of [7] on the level of crystals for the twisted cases under the assumption that the KR crystals for the untwisted algebras exist. In unpublished work, Naito and Sagaki did the same construction for the twisted cases on the Demazure modules.

Remark 2. Assuming that $B^{r, c_{r} s}$ exists, the Demazure crystal $D\left(c_{r} \omega_{r}, s\right)$ and the KR crystal $B^{r, c_{r} s}$ have the same classical crystal structure.

In this paper we assume that the KR crystal $B^{r, c_{r} s}$ has the properties of Assumption 1, which we expect to hold if the KR crystals exist. In the next section we will see that with these assumptions the Demazure crystal sits inside the KR crystal (see Theorem 4.4) and that the KR crystal is unique (see Corollary 4.6). For types $B_{n}^{(1)}, D_{n}^{(1)}$, and $A_{2 n-1}^{(2)}$ let $\sigma$ be the Dynkin automorphism exchanging the Dynkin nodes 0 and 1 and fixing all others. For types $C_{n}^{(1)}$ and $D_{n+1}^{(2)}$ let $\sigma$ be the Dynkin automorphism defined by $i \mapsto n-i$ for all $i \in I$. We also write $\sigma$ for the induced automorphism of $P$.

Assumption 1. The KR crystal $B^{r, c_{r} s}$ has the following properties:
(1) $B^{r, c_{r} s}$ is regular.
(2) There is a unique element $u \in B^{r, c_{r} s}$ such that

$$
\varepsilon(u)=s \Lambda_{0} \quad \text { and } \quad \varphi(u)=s \Lambda_{\tau(0)},
$$

where $t_{-c_{r} \omega_{r}}=w \tau$ with $w \in W$ and $\tau \in \Sigma$.
(3) For all types different from $A_{2 n}^{(2)}, B^{r, c_{r} s}$ admits the automorphism corresponding to $\sigma$ (also denoted $\sigma$ ) such that

$$
\begin{equation*}
\varepsilon \circ \sigma=\sigma \circ \varepsilon, \quad \varphi \circ \sigma=\sigma \circ \varphi \tag{3.3}
\end{equation*}
$$

For type $A_{2 n}^{(2)}$ we assume that $B^{r, c_{r} s}$ is given explicitly by the virtual crystal construction in [23].

## 4. Relation between Demazure and KR crystals

In this section we show that the Demazure crystal sits inside the KR crystals in Theorem 4.4 and, assuming their existence, that the KR crystals are unique in Corollary 4.6.

The main technique that we use in the proof is a decomposition of the translation elements $t_{-c_{r} \omega_{r}}$ that ends in a word for the subalgebra associated to the nodes $\{0,1, \ldots, r-1\}$ of the Dynkin diagram in analogy to the results of [5].

Proposition 4.1. Let $\mathfrak{g}$ be of nonexceptional affine type, $r \in I \backslash I^{0}$ and $t_{-c_{r} \omega_{r}}=w \tau$ for $w \in W$ and $\tau \in \Sigma$. Then a reduced word for the minimum length coset representative $w_{2}$ in $W_{0} w$ is given by

$$
w_{2}= \begin{cases}\prod_{k=i}^{1} s_{0}\left(s_{2} s_{3} \cdots s_{2 k-1}\right)\left(s_{1} s_{2} \cdots s_{2 k-2}\right) & \text { for } r=2 i \text { and } B_{n}^{(1)}, D_{n}^{(1)}, A_{2 n-1}^{(2)},  \tag{4.1}\\ \prod_{k=i}^{1} s_{0}\left(s_{2} s_{3} \cdots s_{2 k}\right)\left(s_{1} s_{2} \cdots s_{2 k-1}\right) & \text { for } r=2 i+1 \text { and } B_{n}^{(1)}, D_{n}^{(1)}, A_{2 n-1}^{(2)}, \\ \prod_{k=i}^{1} s_{0}\left(s_{1} s_{2} \cdots s_{k-1}\right) & \text { for } r=i \text { and } C_{n}^{(1)}, A_{2 n}^{(2)}, D_{n+1}^{(2)}\end{cases}
$$

where the index $k$ decreases as the product is formed from left to right.

Proof. All nodes for $A_{n}^{(1)}$ are special so we may assume $\mathfrak{g}$ is not of this type.
Applying the sequence of reflections in (4.1) to $\Lambda_{\tau(0)}$, we see that each reflection $s_{j}$ changes the weight by a positive multiple of $\alpha_{j}$, and the final weight is $\Lambda_{0}+c_{r} \omega_{r}-i \delta$. It follows that (4.1) yields a reduced decomposition of some element $w_{2} \in W$.

Using (2.3), in all cases we have

$$
w \Lambda_{\tau(0)}=t_{-c_{r} \omega_{r}} \tau^{-1} \Lambda_{\tau(0)}=\Lambda_{0}-c_{r} \omega_{r}-i \delta / a_{0}
$$

Since $r \notin I^{0}$ we have $w_{0}^{\omega_{r}} \omega_{r}=-\omega_{r}$ where $w_{0}^{\omega_{r}}$ is defined in (2.11). Moreover, $w_{0}^{\omega_{r}}$ is also the shortest element of $W_{0}$ sending $\Lambda_{0}+c_{r} \omega_{r}-i \delta / a_{0}$ to $\Lambda_{0}-c_{r} \omega_{r}-i \delta / a_{0}$. It follows that $w=$ $w_{0}^{\omega_{r}} w_{2}$ is a length-additive factorization and that $w_{2}$ is the minimum length coset representative in $W_{0} w$.

Remark 3. Let $K=\{0,1, \ldots, r-1\} \subset I, \mathfrak{g}_{K} \subset \mathfrak{g}$ the simple subalgebra with Dynkin nodes $K$, $\left\{\widetilde{\omega}_{j} \mid j \in K\right\}$ the fundamental weights for $\mathfrak{g}_{K}$, and $W_{K}=\left\langle s_{j} \mid j \in K\right\rangle \subset W$ the Weyl group of $\mathfrak{g}_{K}$. This given, we have $w_{2}=w_{0}^{\widetilde{\omega}_{(0)}}$ where $w_{0}^{\widetilde{\omega}_{j}} \in W_{K}$ is defined with respect to $\mathfrak{g}_{K}$.

Lemma 4.2. All of the weights of $B^{r, c_{r} s}$ are in the convex hull of the $W_{0}$-orbit $W_{0} \cdot c_{r} s \omega_{r}$. Moreover, for every $\mu \in W_{0} \cdot c_{r} s \omega_{r}$, there is a unique element $u_{\mu} \in B\left(c_{r} s \omega_{r}\right) \subset B^{r, c_{r} s}$ of the extremal weight $\mu$.

Proof. By [5,22] the classical decomposition of $D\left(c_{r} \omega_{r}, s\right)$ agrees with that specified in [7]. In every case the above condition holds.

Lemma 4.3. Let $\mathfrak{g}$ be of nonexceptional affine type, $r \in I \backslash I^{0}, s \in \mathbb{Z}_{>0}$, $k<r$ where $B\left(c_{r} s \omega_{k}\right)$ occurs in $B^{r, c_{r} s}$, and $b=u_{c_{r} s \omega_{k}} \in B\left(c_{r} s \omega_{k}\right) \subset B^{r, c_{r} s}$. Define

$$
y= \begin{cases}S_{2} \cdots S_{k+1} S_{1} \cdots S_{k}(b) & \text { for } B_{n}^{(1)}, D_{n}^{(1)}, A_{2 n-1}^{(2)} \\ S_{1} \cdots S_{k}(b) & \text { for } C_{n}^{(1)}, D_{n+1}^{(2)}, A_{2 n}^{(2)}\end{cases}
$$

Then

$$
f_{0}^{s}(y)= \begin{cases}u_{c_{r} s \omega_{k+2}} & \text { for } B_{n}^{(1)}, D_{n}^{(1)}, A_{2 n-1}^{(2)}  \tag{4.2}\\ u_{c_{r} s \omega_{k+1}} & \text { for } C_{n}^{(1)}, D_{n+1}^{(2)}, A_{2 n}^{(2)}\end{cases}
$$

Proof. By definition the element $y$ is an extremal weight vector within the classical crystal $B\left(c_{r} s \omega_{k}\right)$. By weight considerations one may check that

$$
y= \begin{cases}f_{2}^{s} \cdots f_{k}^{s} f_{k+1}^{s} f_{1}^{s} f_{2}^{s} \cdots f_{k-1}^{s} f_{k}^{s}(b) & \text { for } B_{n}^{(1)}, D_{n}^{(1)}, A_{2 n-1}^{(2)}, \\ f_{1}^{c_{r} s} f_{2}^{c_{r} s} \cdots f_{k}^{c_{r} s}(b) & \text { for } C_{n}^{(1)}, D_{n+1}^{(2)}, A_{2 n}^{(2)} .\end{cases}
$$

We claim that

$$
\begin{array}{lll}
\varepsilon(y)=s\left(\Lambda_{0}+\Lambda_{2}\right), & \varphi(y)=s\left(\Lambda_{0}+\Lambda_{k+2}\right), & \text { for } B_{n}^{(1)}, D_{n}^{(1)}, A_{2 n-1}^{(2)}, k>0, \\
\varepsilon(y)=s\left(\Lambda_{0}+c_{r} \Lambda_{1}\right), & \varphi(y)=s\left(\Lambda_{0}+c_{r} \Lambda_{k+1}\right), & \text { for } C_{n}^{(1)}, A_{2 n}^{(2)}, D_{n+1}^{(2)}, k>0 \\
\varepsilon(y)=s \Lambda_{0}, & \varphi(y)=s \Lambda_{0}, & \text { for } k=0 .
\end{array}
$$

By extremality and Lemma 4.2, $y$ is in the indicated position within its $i$-strings for $i \in I \backslash\{0\}$. It remains to show that $\varepsilon_{0}(y)=\varphi_{0}(y)=s$ and (4.2) holds. In each case we shall use Assumption 1(3) either for the existence of a crystal automorphism $\sigma$ on $B^{r, c_{r} s}$ or, in type $A_{2 n}^{(2)}$, for the virtual crystal construction of $B^{r, c_{r} s}$.

We begin with type $D_{n}^{(1)}$. We have $c_{r}=1$ and $\mu:=\mathrm{wt}(y)=\left(0^{2}, s^{k}, 0^{n-k-2}\right)$. Here we realize $P_{0} \subset((1 / 2) \mathbb{Z})^{n}$ with $i$ th standard basis element $\epsilon_{i}$, with $\omega_{i}=\left(1^{i}, 0^{n-i}\right)$ for $1 \leqslant i \leqslant n-2$ (we do not need the spin weights) and $\alpha_{i}=\epsilon_{i}-\epsilon_{i+1}$ for $1 \leqslant i \leqslant n-1$. Let $b^{\prime}=u_{s \omega_{k+2}} \in B\left(s \omega_{k+2}\right) \subset$ $B^{r, s}$. We have $\varphi_{0}\left(b^{\prime}\right)=0$, for otherwise $f_{0}\left(b^{\prime}\right) \in B^{r, s}$ has weight contradicting Lemma 4.2. Since $\left\langle\alpha_{0}^{\vee}, \operatorname{wt}\left(b^{\prime}\right)\right\rangle=2 s$, we have $\varepsilon_{0}\left(b^{\prime}\right)=2 s$.

For type $D_{n}^{(1)}$, the automorphism $\sigma$ of $B^{r, c_{r} s}$ satisfies $e_{0}=\sigma \circ e_{1} \circ \sigma$. Define $z=e_{1}^{s}\left(\sigma\left(b^{\prime}\right)\right)$. It suffices to show that

$$
y=\sigma(z)
$$

Let $K=\{2,3, \ldots, n\} \subset I$. The subalgebra of $\mathfrak{g}$ with simple roots $\alpha_{i}$ for $i \in K$, is of type $D_{n-1}$. For this reason we shall refer to $D_{n-1}$-components and $D_{n-1}$-highest weight vectors instead of $K$-components and $K$-highest weight vectors. Our proof rests on the following fact:
$B^{r, s}$ contains a unique element of weight $\mu$ that satisfies $\varepsilon_{1}=0$ and whose associated $D_{n-1^{-}}$ highest weight vector has $D_{n}$-weight $\lambda:=\left(0, s^{k}, 0^{n-k-1}\right)$.

For the classical components of $B^{r, s}$ that contain $D_{n-1}$-components of weight $\lambda$, are precisely those of the form $B\left((s-t) \omega_{k}+t \omega_{k+2}\right)$ for $0 \leqslant t \leqslant s$, and only for $t=0$ does the classical component contain an element of weight $\mu$ with $\varepsilon_{1}=0$ (and by extremality $B\left(s \omega_{k}\right)$ contains a unique element of weight $\mu$ ).
$y$ clearly satisfies the above property. It suffices to show that $\sigma(z)$ does also.
$\sigma\left(b^{\prime}\right)$ is a $D_{n-1}$-highest weight vector with $\operatorname{wt}\left(\sigma\left(b^{\prime}\right)\right)=\left(-s, s^{k+1}, 0^{n-k-2}\right)$. So $\operatorname{wt}(z)=\mu$. By weight considerations and Lemma $4.2, z^{\prime}=S_{k+1} \cdots S_{2}(z)$ is a $D_{n-1}$-highest weight vector of weight $\lambda$. Therefore, $\sigma(z)$ has weight $\sigma(\mu)=\mu$ and has associated $D_{n-1}$-highest weight vector $\sigma\left(z^{\prime}\right)$, which has weight $\sigma(\lambda)=\lambda$. Since the Dynkin nodes 0 and 1 are nonadjacent we have $\varepsilon_{1}(\sigma(z))=\varepsilon_{1}\left(e_{0}^{s}\left(b^{\prime}\right)\right)=\varepsilon_{1}\left(b^{\prime}\right)=0$. Thus $\sigma(z)$ fulfills the above criteria and so must be equal to $y$.

The proof is analogous for types $B_{n}^{(1)}$ and $A_{2 n-1}^{(2)}$ using the same set $K$, which defines subalgebras of types $B_{n-1}$ and $C_{n-1}$, respectively.

For type $C_{n}^{(1)}$ we have $c_{r}=2$ for all $1 \leqslant r \leqslant n-1$. Let $K=\{1,2, \ldots, n-1\}$; the associated subalgebra is of type $A_{n-1}$. Here we realize $P_{0} \cong \mathbb{Z}^{n}$ with $\omega_{i}=\left(1^{i}, 0^{n-i}\right)$ for $1 \leqslant i \leqslant n$ and $\alpha_{i}=\epsilon_{i}-\epsilon_{i+1}$ for $1 \leqslant i \leqslant n-1$ and $\alpha_{n}=2 \epsilon_{n}$. Our argument uses the fact that
$B^{r, 2 s}$ contains a unique element of weight $\mu:=\left(0,(2 s)^{k}, 0^{n-k-1}\right)$ such that $\varepsilon_{n}=0$ and whose associated $A_{n-1}$-highest weight vector has $C_{n}$-weight $2 s \omega_{k}$.

For the classical components in $B^{r, 2 s}$ that contain such an $A_{n-1}$-component, are precisely those of the form $B\left(2(s-t) \omega_{k}+2 t \omega_{k+1}\right)$ for $0 \leqslant t \leqslant s$, and among these, only for $t=0$ does the classical component contain an element of weight $\mu$ for which $\varepsilon_{n}=0$ (and by extremality $B\left(2 s \omega_{k}\right)$ contains a unique element of weight $\mu$ ).

By construction $y$ satisfies this property. It suffices to show that $\sigma(z)$ does also, where $z=$ $e_{n}^{s} \circ \sigma\left(b^{\prime}\right)$ and $b^{\prime}=u_{2 s \omega_{k+1}} \in B\left(2 s \omega_{k+1}\right) \subset B^{r, s}$.

We have $\varphi_{0}\left(b^{\prime}\right)=0$ for otherwise $f_{0}\left(b^{\prime}\right) \in B^{r, 2 s}$ would have weight contradicting Lemma 4.2. Since $\left\langle\alpha_{0}^{\vee}, \operatorname{wt}\left(b^{\prime}\right)\right\rangle=2 s$ we have $\varepsilon_{0}\left(b^{\prime}\right)=2 s$.
$\sigma\left(b^{\prime}\right)$ is an $A_{n-1}$-highest weight vector of weight $\sigma\left(2 s \omega_{k+1}\right)=\left(0^{n-k-1},(-2 s)^{k+1}\right)$. Therefore, $z$ has weight $\left(0^{n-k-1},(-2 s)^{k}, 0\right)$ and associated $A_{n-1}$-highest weight vector $z^{\prime}=$ $S_{n-k} \cdots S_{n-1}(z)$, which has weight $\left(0^{n-k},(-2 s)^{k}\right)$. It follows that $\sigma(z)$ has weight $\mu$ and its associated $A_{n-1}$-highest weight vector has weight $2 s \omega_{k}$. Now $\varepsilon_{n}(\sigma(z))=\varepsilon_{n}\left(e_{0}^{s}\left(b^{\prime}\right)\right)=\varepsilon_{n}\left(b^{\prime}\right)=0$ since the Dynkin nodes 0 and $n$ are nonadjacent. We have shown that $\sigma(z)$ satisfies the above criteria and so must be equal to $y$.

Type $D_{n+1}^{(2)}$ is similar to type $C_{n}^{(1)}$.
For type $A_{2 n}^{(2)}$, the above kind of argument is not available since $A_{2 n}^{(2)}$ admits no nontrivial Dynkin automorphism. Instead we apply virtual crystals. Under Assumption 1(3), by [23] the crystal $B^{r, s}$ is realized as the subset of $V^{r, s}=B_{A}^{2 n-r, s} \otimes B_{A}^{r, s}$ of type $A_{2 n-1}^{(1)}$ generated from $u_{s \omega_{2 n-r}} \otimes u_{s \omega_{r}}$ by the virtual crystal operators $\hat{f_{i}}=f_{i} f_{2 n-i}$ for $1 \leqslant i \leqslant n$ and $\hat{f}_{0}=f_{0}^{2}$ where $f_{i}$ are the crystal operators of the $A_{2 n-1}^{(1)}$-crystal $V^{r, s}$. Denote the virtualization by $v: B^{r, s} \hookrightarrow V^{r, s}$. We perform explicit computations using the tableau realization of $U_{q}\left(A_{2 n-1}\right)$-crystals in [19] and 0 -arrows given by [24]. We have

$$
\begin{gathered}
v(b)=(2 n-k)^{s} \cdots(r+2)^{s}(r+1)^{s} k^{s} \cdots 2^{s} 1^{s} \otimes r^{s} \cdots 2^{s} 1^{s} \\
v(y)=(2 n)^{s}(2 n-k-1)^{s} \cdots(r+2)^{s}(r+1)^{s}(k+1)^{s} \cdots 3^{s} 2^{s} \otimes r^{s} \cdots 2^{s} 1^{s} \\
v\left(f_{0}^{s} y\right)=(2 n-k-1)^{s} \cdots(r+2)^{s}(r+1)^{s}(k+1)^{s} \cdots 2^{s} 1^{s} \otimes r^{s} \cdots 2^{s} 1^{s}=v\left(u_{s \omega_{k+1}}\right)
\end{gathered}
$$

The next theorem is the main result of this paper. It shows that under the isomorphism between the Demazure and the KR crystals as classical crystals zero arrows map to zero arrows. In addition it yields the isomorphism (4.3) without the assumption that the KR crystal $B^{r, c_{r} s}$ is perfect.

Theorem 4.4. Let $(r, s) \in I \backslash\{0\} \times \mathbb{Z}_{>0}$. Suppose that $r \in I^{0}$, or $c_{r} \omega_{r}=\theta$, or $\mathfrak{g}$ is of nonexceptional affine type. Write $t_{-c_{r} \omega_{r}^{*}}=w \tau$ with $w \in W$ and $\tau \in \Sigma$. Then there is an affine crystal isomorphism

$$
\begin{align*}
B\left(s \Lambda_{\tau(0)}\right) & \cong B^{r, c_{r} s} \otimes B\left(s \Lambda_{0}\right) \\
u_{s \Lambda_{\tau(0)}} & \mapsto u^{\prime}:=u \otimes u_{s \Lambda_{0}} \tag{4.3}
\end{align*}
$$

where $u$ is the element specified by Assumption 1(2). It restricts to an isomorphism

$$
\begin{equation*}
D\left(c_{r} \omega_{r}, s\right) \cong B^{r, c_{r} s} \otimes u_{s \Lambda_{0}} \tag{4.4}
\end{equation*}
$$

where both sides of (4.4) are regarded as full subcrystals of their respective sides in (4.3).

Proof. Let $w_{2}$ be the minimum length coset representative in $W_{0} w$. Then $w=w_{1} w_{2}$ is a lengthadditive factorization with $w_{1}=w w_{2}^{-1} \in W_{0}$. We choose a reduced word of $w$ by concatenating reduced words of $w_{1}$ and $w_{2}$. We claim that it suffices to establish the following assertions.
(A1) There is a bijection

$$
\begin{align*}
B_{w_{2}}\left(s \Lambda_{\tau(0)}\right) & \rightarrow B^{\prime}:=f_{w_{2}}\left(u^{\prime}\right), \\
u_{s \Lambda_{\tau(0)}} & \mapsto u^{\prime} \tag{4.5}
\end{align*}
$$

that preserves all arrows in $f_{w_{2}}$.
(A2) $B^{\prime} \subset B^{r, c_{r} s} \otimes u_{s \Lambda_{0}}$.

Suppose (A1) and (A2) hold. Since $w_{1} \in W_{0}, B_{w_{2}}\left(s \Lambda_{\tau(0)}\right)$ contains all the classical highest weight vectors of $D\left(c_{r} \omega_{r}, s\right)$. By (A1) these classical highest weight vectors correspond to the classical highest weight vectors in $B^{\prime}$. Let $B^{\prime \prime} \subset B^{r, c_{r} s} \otimes B\left(s \Lambda_{0}\right)$ be the classical subcrystal generated by $B^{\prime}$; by (A2) $B^{\prime \prime} \subset B^{r, c_{r} s} \otimes u_{s \Lambda_{0}}$. By Demazure theory for highest weight modules over simple Lie algebras, the bijection (4.5) extends uniquely to a classical crystal isomorphism $D\left(c_{r} \omega_{r}, s\right) \cong B^{\prime \prime}$. By Assumption 1 and Remark 2 we have $B^{\prime \prime}=B^{r, c_{r} s} \otimes u_{s \Lambda_{0}}$. So we have a bijection

$$
\begin{equation*}
D\left(c_{r} \omega_{r}, s\right) \cong B^{r, c_{r} s} \otimes u_{s \Lambda_{0}} \tag{4.6}
\end{equation*}
$$

which is an isomorphism of classical crystals that extends the bijection (4.5). It follows that $B^{r, c_{r} s} \otimes u_{s \Lambda_{0}}$ and, therefore, $B^{r, c_{r} s} \otimes B\left(s \Lambda_{0}\right)$, have a unique affine highest weight vector, namely, $u^{\prime}$. By [17, Proposition 2.4.4] there is an affine crystal isomorphism (4.3). It must extend the bijection (4.6), and the theorem follows.

We prove (A1) and (A2) by cases.
If $r \in I^{0}$ then by (2.10) $w_{2}$ is the identity, $B_{w_{2}}\left(s \Lambda_{\tau(0)}\right)=\left\{u_{s \Lambda_{\tau(0)}}\right\}, B^{\prime}=\left\{u^{\prime}\right\}, c_{r}=1$, and $B^{r, s} \cong B\left(s \omega_{r}\right)$ as a classical crystal with classical highest weight vector $u$. In this case (A1) and (A2) are immediate. This is the only case where $\omega_{r}^{*} \neq \omega_{r}$.

If $c_{r} \omega_{r}=\theta$ then $\tau$ is the identity, $w_{1}=s_{\theta}$ and $w_{2}=s_{0}$. By Assumption $1(2), B_{w_{2}}\left(s \Lambda_{0}\right)$ and $B^{\prime}$ are the 0 -strings of $u_{s \Lambda_{0}}$ and $u^{\prime}$, respectively. The elements are at the dominant ends of their respective 0 -strings, which both have length $s$. This gives (A1). (A2) follows by the signature rule and Assumption 1(2).

Otherwise we assume that $\mathfrak{g}$ is of nonexceptional affine type and $r \in I \backslash I^{0}$. Then $w_{2}$ is given in Proposition 4.1. We use the notation of Remark 3 throughout the rest of the proof. Since $K \subsetneq I, \mathfrak{g}_{K}$ is a simple Lie algebra and Assumption 1(1) implies that $B^{r, c_{r} s}$ decomposes into a
direct sum of $K$-components, each of which is isomorphic to the crystal graph of an irreducible highest weight module for $U_{q}\left(\mathfrak{g}_{K}\right)$. We have the $K$-crystal isomorphisms

$$
\begin{equation*}
B_{w_{2}}\left(s \Lambda_{\tau(0)}\right) \cong B_{w_{2}}\left(s \widetilde{\omega}_{\tau(0)}\right)=B\left(s \widetilde{\omega}_{\tau(0)}\right) \cong B^{\prime} \tag{4.7}
\end{equation*}
$$

The first isomorphism holds by restriction from an $I$-crystal to a $K$-crystal. The equality holds by Remark 3 and Demazure theory for the simple Lie algebra $\mathfrak{g}_{K}$. We have $B_{w_{2}}\left(\widetilde{\omega}_{\tau(0)}\right) \cong B^{\prime}$, since both sides are generated by $f_{w_{2}}$ (with $w_{2} \in W_{K}$ ) applied to $K$-highest weight vectors of $K$-weight $s \widetilde{\omega}_{\tau(0)}$; see Assumption 1(2). This establishes (A1).

For types $D_{n}^{(1)}, B_{n}^{(1)}, A_{2 n-1}^{(2)}$ we have $c_{r}=1$ for all $r$ and $\tau=\tau_{0}$ or $\tau=\tau_{1}$ (and $\tau(0)=0$ or $\tau(0)=1)$ according as $r$ is even or odd. Here $u=u_{s \omega_{\tau(0)}} \in B\left(s \omega_{\tau(0)}\right) \subset B^{r, c_{r} s}$, where $\omega_{0}=0$ by convention.

We consider the decomposition of $B^{r, c_{r} s}$ into $K$-components, which we call $D_{r}$-components. Note that 0 and 1 are the spinor nodes in $D_{r}$. Now $u_{c_{r} s \omega_{r}} \in B^{r, c_{r} s}$ is a $D_{r}$-lowest weight vector of $D_{r}$-weight $-2 s \widetilde{\omega}_{0}$. Therefore, there is a $D_{r}$-crystal embedding

$$
\begin{aligned}
B\left(2 s \widetilde{\omega}_{0}\right) \otimes u_{s \Lambda_{0}} & \rightarrow B\left(s \widetilde{\omega}_{\tau(0)}\right)^{\otimes 2} \otimes B\left(s \Lambda_{0}\right) \\
u_{c_{r} s \omega_{r}} \otimes u_{s \Lambda_{0}} & \mapsto u_{-s \widetilde{\omega}_{0}}^{\otimes 2} \otimes u_{s \Lambda_{0}}
\end{aligned}
$$

But by Lemma 4.3 there is a $D_{r}$-path from $u^{\prime}$ to $u_{c_{r} s \omega_{r}} \otimes u_{s \Lambda_{0}}$ that never changes the right-hand tensor factor. Therefore, there is a $D_{r}$-embedding

$$
\begin{aligned}
B^{\prime} & \rightarrow B\left(s \widetilde{\omega}_{\tau(0)}\right)^{\otimes 2} \otimes B\left(s \Lambda_{0}\right), \\
u^{\prime}=u \otimes u_{s \Lambda_{0}} & \mapsto u_{s} \widetilde{\omega}_{\tau(0)} \otimes u_{-s \widetilde{\omega}_{0}} \otimes u_{s \Lambda_{0}} .
\end{aligned}
$$

The image of $u^{\prime}$ is uniquely determined by Assumption 1(2) since $u_{s \widetilde{\omega}_{\tau(0)}} \otimes u_{-s \widetilde{\omega}_{0}}$ is the unique element of $B\left(s \widetilde{\omega}_{\tau(0)}\right)^{\otimes 2}$ with $\varepsilon=s \Lambda_{0}$ and $\varphi=s \Lambda_{\tau(0)}$.

The form of the image of $u^{\prime}$ now clearly shows that when $f_{w_{2}}$ is applied to $u^{\prime}$ it only acts on the left-hand tensor factor. This implies (A2).

Next let us consider type $C_{n}^{(1)}$ for $r \notin I^{0}$; for such $r, c_{r}=2$ and $\tau$ is the identity. Here $u$ is the unique element in the one-dimensional $C_{n}$-crystal in $B^{r, 2 s}$. We decompose $B^{r, 2 s}$ as a $K$-crystal, which is a $C_{r}$-crystal in this case. All other arguments go through as for type $D_{n}^{(1)}$.

Types $D_{n+1}^{(2)}$ and $A_{2 n}^{(2)}$ follow in the same fashion. In this case the decomposition of $B^{r, c_{r} s}$ as a $K$-crystal is a $B_{r}$ crystal.

Remark 4. We expect Theorem 4.4 to hold for any affine algebra $\mathfrak{g}$ and any Dynkin node $r \in$ $I \backslash\{0\}$. Our proof requires a special property, that the minimum length coset representative $w_{2}$ of Proposition 4.1 has a certain form, namely, in the notation of (2.11), $w_{2}=w_{0}^{\lambda}$ where $\lambda$ is a fundamental weight for some subalgebra $\mathfrak{g}_{K}$ where $K \subsetneq I$. This property of $w_{2}$ does not hold for the trivalent node in type $E_{6}^{(1)}$. For such nodes a different strategy is required.

Remark 5. In the notation of Lemma 2.3 we expect that for any affine algebra $\mathfrak{g}$ with affine Dynkin diagram $X$ and any $\sigma \in \operatorname{Aut}(X)$, there is a bijection $\sigma: B^{r, c_{r} s} \rightarrow B^{\sigma^{\prime}(r), c_{r} s}$ such that (3.3) holds. In particular, for any $\sigma \in \operatorname{Aut}(X)$, we expect that there is an automorphism $\sigma$ on $B^{r, c_{r} s}$
satisfying (3.3) if and only if $\sigma^{\prime}(r)=r$. By Remark 1 this means that every special Dynkin automorphism $\sigma \in \Sigma$ should induce an automorphism of each $B^{r, c_{r} s}$. In contrast, for the nonspecial automorphism $\sigma=(0,1)$ of $D_{n}^{(1)}, \sigma^{\prime}=(n-1, n)$ is not the identity and $\sigma$ induces a bijection $B^{n-1, s} \rightarrow B^{n, s}$ satisfying (3.3).

Remark 5 comes into play in Section 6 and the following theorem.
Theorem 4.5. For the cases in Assumption 1(3) where $\sigma$ is defined, there exist unique maps

$$
\Psi: D\left(\omega_{r}, s\right) \hookrightarrow B^{r, c_{r} s} \quad \text { and } \quad \Psi^{\sigma}: D^{\sigma}\left(\omega_{r}, s\right) \hookrightarrow B^{r, c_{r} s} .
$$

The maps are induced by $\Psi\left(u_{s \Lambda_{0}}\right)=u$ and $\Psi^{\sigma}\left(u_{s \Lambda_{\sigma(0)}}\right)=\sigma(u)$.
Proof. The map $\Psi^{\sigma}$ is obtained by applying $\sigma$ to everything in sight.
Corollary 4.6. The affine structure of $B^{r, c_{r} s}$ is uniquely determined.
Theorem 4.7. Suppose that $\lambda=\sum_{r \in I \backslash\{0\}} m_{r} c_{r} \omega_{r}$ with $m_{r} \in \mathbb{Z}_{\geqslant 0}$ and $m_{r}>0$ only when $r$ is as in Theorem 4.4. Write $t_{-\lambda^{*}}=w \tau$ for $w \in W$ and $\tau \in \Sigma$. Assume that for each $k \in I^{0}$ and every $r \in I \backslash\{0\}$ with $m_{r}>0$, the special Dynkin automorphism $\tau_{k} \in \Sigma$ induces an automorphism of $B^{r, c_{r} s}$ that sends $i$-arrows to $\tau_{k}(i)$-arrows. Then for every $r^{\prime} \in I^{0}$ there is an isomorphism

$$
B\left(s \Lambda_{\tau\left(r^{\prime}\right)}\right) \cong\left(\bigotimes_{r \in I \backslash\{0\}}\left(B^{r, c_{r} s}\right)^{\otimes m_{r}}\right) \otimes B\left(s \Lambda_{r^{\prime}}\right)
$$

which restricts to an isomorphism of full subcrystals

$$
B_{\tau_{r^{\prime}}^{-1} w \tau_{r^{\prime}}}\left(s \Lambda_{\tau\left(r^{\prime}\right)}\right) \cong\left(\bigotimes_{r \in I \backslash\{0\}}\left(B^{r, c_{r} s}\right)^{\otimes m_{r}}\right) \otimes u_{s \Lambda_{r^{\prime}}}
$$

Proof. Induction allows a straightforward reduction to the case of one KR tensor factor. Applying a special Dynkin automorphism allows the reduction to the case $r^{\prime}=0$, which is Theorem 4.4.

Corollary 4.8. Let $\lambda$ be as in Theorem 4.7. Then the Demazure crystal $D(\lambda, s)$ can be extended to a full affine crystal by adding 0-arrows.

Remark 6. This proves Conjecture 1 in [5] on the level of crystals. However it is not yet clear whether there exists a global basis of the Demazure module, whose corresponding crystal basis is the one given in Theorem 4.7. For level $s=1$, Theorem 4.7 was proved using the Littelmann path model in [6, Proposition 3].

## 5. Reaching the classical highest weight vectors of a KR crystal

In the proof of Lemma 4.3, explicit paths in the KR crystal were given, from the element $u$ to certain classical highest weight vectors in the KR crystal. For $\mathfrak{g}$ of nonexceptional affine type and
for each KR crystal $B^{r, c_{r} s}$, we shall give (without proof) an explicit way to reach each classical highest weight vector in $B^{r, c_{r} s}$ from the element $u$ of Assumption 1.

If $r \in I^{0}$ then the KR crystal $B^{r, c_{r} s}$ is connected as a classical crystal and the problem is trivial. This includes all $r \in I \backslash\{0\}$ for $A_{n}^{(1)}$.

So we now assume $r \notin I^{0}$.
We shall use the standard realizations of the weight lattices of $B_{n}, C_{n}, D_{n}$ by sublattices of $((1 / 2) \mathbb{Z})^{n}$. We let $\omega_{i}=\left(1^{i}, 0^{n-i}\right)$ for $i \in I \backslash\{0\}$ nonspin. Since $r \notin I^{0}$ the only spin weight we need is $\omega_{n}=(1 / 2)\left(1^{n}\right)$ in type $B_{n}$, and in that case $c_{n}=2$. Thus all the weights we must consider, correspond to partitions, elements in $\mathbb{Z}_{\geqslant 0}^{n}$ consisting of weakly decreasing sequences. Moreover, for the nonexceptional affine algebras the KR crystals are multiplicity-free as classical crystals.

For $\mathfrak{g}$ of type $B_{n}^{(1)}, D_{n}^{(1)}$, or $A_{2 n-1}^{(2)}, B(\lambda)$ occurs in $B^{r, c_{r} s}$ if and only if the diagram of the partition corresponding to $\lambda$, is obtained from the $r \times s$ rectangular partition by removing vertical dominoes. Let $t=0$ or $t=1$ according as $r$ is even or odd. We have

$$
u_{\lambda}=\left(\prod_{i=(r-t) / 2}^{1} f_{0}^{\lambda_{2 i}}\left(f_{2}^{\lambda_{2 i}} f_{3}^{\lambda_{2 i}} \cdots f_{2 i-1+t}^{\lambda_{2 i}}\right)\left(f_{1}^{\lambda_{2 i}} f_{2}^{\lambda_{2 i}} \cdots f_{2 i-2+t}^{\lambda_{2 i}}\right)\right) u
$$

where the product is formed from left to right using decreasing indices $i$.
Example 1. Let $\mathfrak{g}$ be of type $D_{7}^{(1)},(r, s)=(5,4)$ and $\lambda$ be the weight $\omega_{5}+\omega_{3}+2 \omega_{1}$. Then $t=1, \lambda$ is the partition $(4,2,2,1,1)$, and the sequence of lowering operators is $\left(f_{0} f_{2} f_{3} f_{4} f_{1} f_{2} f_{3}\right)\left(f_{0}^{2} f_{2}^{2} f_{1}^{2}\right)$. This is applied to the classical highest weight vector of weight given by the partition (4), and the parenthesized subexpressions successively yield classical highest weight vectors corresponding to the partitions $(4,2,2)$, and $(4,2,2,1,1)$, respectively.

For $\mathfrak{g}$ of type $C_{n}^{(1)}, A_{2 n}^{(2)}$ or $D_{n+1}^{(2)}$, the partitions corresponding to classical highest weights in $B^{r, c_{r} s}$ are precisely those of the form $c_{r} \lambda=\left(c_{r} \lambda_{1}, c_{r} \lambda_{2}, \ldots\right)$ where $\lambda$ runs over the partitions contained in the $r \times s$ rectangle. We have

$$
u_{c_{r} \lambda}=\left(\prod_{i=r}^{1} f_{0}^{c_{r} \lambda_{i}} f_{1}^{c_{r} \lambda_{i}} \cdots f_{i-1}^{c_{r} \lambda_{i}}\right) u
$$

where the product of operators is formed from left to right as $i$ decreases.
Example 2. Let $\mathfrak{g}$ be of type $C_{3}^{(1)},(r, s)=(2,3)$, and $\lambda=\omega_{2}+2 \omega_{1}$. Then we have $c_{r}=2$, the partition $\lambda=(3,1)$, and the sequence of lowering operators $\left(f_{0}^{2} f_{1}^{2}\right)\left(f_{0}^{6}\right)$. This is applied to the classical highest weight vector of weight 0 (corresponding to the empty partition). After $f_{0}^{6}$ the classical weight is given by the partition (6) and after $f_{0}^{2} f_{1}^{2}$ one has the partition $(6,2)=2 \lambda$.

## 6. Connectedness

Theorem 4.4 shows that the KR crystals $B^{r, c_{r} s}$ are connected. In this section we show that the tensor product of two KR crystals is also connected by providing an algorithm which for any given element in the crystal yields a string of operators $e_{i}$ (or $f_{i}$ ) to reach a given special element.

This algorithm is also useful in defining crystal morphisms such as the combinatorial $R$-matrix. Since KR crystals and their tensor products are not highest weight crystals, it is not completely obvious which sequence of raising operators $e_{i}$ will yield a given special element.

Here we give a construction on how to reach $u_{1} \otimes u_{2} \in B^{r_{1}, c_{1} s_{1}} \otimes B^{r_{2}, c_{r_{2}} s_{2}}$ where $u_{1}$ is the unique element of $B^{r_{1}, c_{1} s_{1}}$ with $\varepsilon\left(u_{1}\right)=s_{1} \Lambda_{0}$ and $\varphi\left(u_{1}\right)=s_{1} \Lambda_{\tau_{1}(0)}$ as required in Assumption 1(2), and $u_{2}$ is the unique element in $B^{r_{2}, c_{r_{2}} s_{2}}$ with $\varepsilon\left(u_{2}\right)=s_{2} \Lambda_{\tau_{2}^{-1}(0)}$ and $\varphi\left(u_{2}\right)=s_{2} \Lambda_{0}$ as required in Assumption 1(2) and Remark 5.

By Theorems 4.4 and 4.5 we have the following isomorphism of affine crystals

$$
\begin{gathered}
B^{r_{1}, c_{r_{1}} s_{1}} \otimes B^{r_{2}, c_{r_{2}} s_{2}} \otimes B\left(s_{2} \Lambda_{\tau_{2}^{-1}(0)}\right) \\
u_{1} \otimes u_{2} \otimes{u_{s_{2}} \Lambda_{\tau_{2}^{-1}(0)}}^{r_{1}, c_{r_{1}} s_{1}} \otimes u_{1} \otimes u_{s_{2} \Lambda_{0}} .
\end{gathered}
$$

Assume that $s_{1} \geqslant s_{2}$. Acting with raising operators $e_{i}$ with $i \in I$ one can bring any element $b_{1} \otimes b_{2} \otimes u_{s_{2} \Lambda_{\tau_{2}^{-1}(0)}}$ into the form $c_{1} \otimes u_{2} \otimes u_{s_{2} \Lambda_{\tau_{2}^{-1}(0)}}$ since by the tensor product rule the $e_{i}$ will eventually act on the right tensor factors and by Theorem $4.4 b_{2} \otimes u_{s_{2} \Lambda_{\tau_{2}^{-1}(0)}}$ is connected to $u_{2} \otimes u_{s_{2} \Lambda_{\tau_{2}^{1}(0)}}$. Once such an element is reached, tensor from the right by $u_{\left(s_{1}-s_{2}\right) \Lambda_{0}} \in B\left(\left(s_{1}-\right.\right.$ $\left.s_{2}\right) \Lambda_{0}$ ) to obtain

$$
\begin{aligned}
& B^{r_{1}, c_{r_{1}} s_{1}} \otimes B^{r_{2}, c_{r_{2}} s_{2}} \otimes B\left(s_{2} \Lambda_{\tau_{2}^{-1}(0)}\right) \otimes B\left(\left(s_{1}-s_{2}\right) \Lambda_{0}\right) \\
& \quad \cong B^{r_{1}, c_{r_{1}} s_{1}} \otimes B\left(s_{2} \Lambda_{0}\right) \otimes B\left(\left(s_{1}-s_{2}\right) \Lambda_{0}\right)
\end{aligned}
$$

under which $c_{1} \otimes u_{2} \otimes u_{s_{2} \Lambda_{\tau_{2}-1}(0)} \otimes u_{\left(s_{1}-s_{2}\right) \Lambda_{0}}$ maps to $c_{1} \otimes u_{s_{2} \Lambda_{0}} \otimes u_{\left(s_{1}-s_{2}\right) \Lambda_{0}}$. The latter element is the image of the vector $c_{1} \otimes u_{s_{1} \Lambda_{0}}$ under the embedding of affine crystals $B^{r_{1}, c_{r_{1}} s_{1}} \otimes B\left(s_{1} \Lambda_{0}\right) \rightarrow B^{r_{1}, c_{r_{1}} s_{1}} \otimes B\left(\left(s_{1}-s_{2}\right) \Lambda_{0}\right) \otimes B\left(s_{2} \Lambda_{0}\right)$.

Now from $c_{1} \otimes u_{s_{1} \Lambda_{0}} \in B^{r_{1}, c_{r_{1}} s_{1}} \otimes B\left(s_{1} \Lambda_{0}\right)$ one can reach $u_{1} \otimes u_{s_{1} \Lambda_{0}}$ using $e_{i}$ with $i \in I$.
If $s_{1}<s_{2}$ we tensor from the left with the dual crystals. Explicitly,

$$
B^{\vee}\left(s_{1} \Lambda_{\tau_{1}(0)}\right) \otimes B^{r_{1}, c_{r_{1}} s_{1}} \otimes B^{r_{2}, c_{r_{2}} s_{2}} \cong B^{\vee}\left(s_{1} \Lambda_{0}\right) \otimes B^{r_{2}, c_{r_{2}} s_{2}}
$$

The lowest weight element $u_{s_{1} \Lambda_{0}}^{\vee} \in B^{\vee}\left(s_{1} \Lambda_{0}\right)$ corresponds to $u_{s_{1} \Lambda_{\tau_{1}(0)}}^{\vee} \otimes u_{1} \in B^{\vee}\left(s_{1} \Lambda_{\tau_{1}(0)}\right) \otimes$ $B^{r_{1}, c_{r_{1}} s_{1}}$. Acting with lowering operators $f_{i}$ with $i \in I$ one can bring any element $u_{s_{1} \Lambda_{\tau_{1}(0)}}^{\vee} \otimes$ $b_{1} \otimes b_{2}$ into the form $u_{s_{1} \Lambda_{\tau_{1}(0)}}^{\vee} \otimes u_{1} \otimes c_{2}$. Once this element is reached, tensor on the left by $u_{\left(s_{2}-s_{1}\right) \Lambda_{0}}^{\vee} \in B^{\vee}\left(\left(s_{2}-s_{1}\right) \Lambda_{0}\right)$, obtaining the element $u_{\left(s_{2}-s_{1}\right) \Lambda_{0}}^{\vee} \otimes u_{s_{1} \Lambda_{\tau_{1}(0)}}^{\vee} \otimes u_{1} \otimes c_{2}$, which can be identified with $u_{s_{2} \Lambda_{0}}^{\vee} \otimes c_{2} \in B^{\vee}\left(s_{2} \Lambda_{0}\right) \otimes B^{r_{2}, c_{r_{2}} s_{2}}$. Now move down to the lowest weight vector $u_{s_{2} \Lambda_{0}}^{\vee} \otimes u_{2}$ using $f_{i}$ with $i \in I$.

As a result of the above construction we obtain the following corollary:
Corollary 6.1. The tensor product $B^{r_{1}, c_{1} s_{1}} \otimes B^{r_{2}, c_{r_{2}} s_{2}}$ of $K R$ crystals is connected.
The combinatorial $R$-matrix is a crystal morphism. More precisely

$$
R: B^{r_{1}, c_{r_{1}} s_{1}} \otimes B^{r_{2}, c_{r_{2}} s_{2}} \rightarrow B^{r_{2}, c_{r_{2}} s_{2}} \otimes B^{r_{1}, c_{r_{1}} s_{1}}
$$

satisfies $R \circ e_{i}=e_{i} \circ R$ and $R \circ f_{i}=f_{i} \circ R$ for all $i \in I$. There exists a unique element $u_{c_{r_{k}} s_{k} \omega_{r_{k}}} \in B^{r_{k}, c_{r_{k}} s_{k}}$ and by weight considerations $R$ must map $R\left(u_{c_{r_{1}} s_{1} \omega_{r_{1}}} \otimes u_{c_{r_{2}} s_{2} \omega_{r_{2}}}\right)=$ $u_{c_{r_{2}} s_{2} \omega_{r_{2}}} \otimes u_{c_{r_{1}} s_{1} \omega_{r_{1}}}$. Assume that $s_{1} \geqslant s_{2}$. Then for any element $b_{1} \otimes b_{2} \in B^{r_{1}, c_{r_{1}} s_{1}} \otimes B^{r_{2}, c_{r_{2}} r_{2}}$ the above algorithm provides a sequence $e_{\{i\}}:=e_{i_{1}} e_{i_{2}} \cdots e_{i_{\ell}}$ such that $e_{\{i\}}\left(b_{1} \otimes b_{2}\right)=u_{1} \otimes u_{2}$. In particular, $e_{\{j\}}\left(u_{c_{r_{1}} s_{1} \omega_{r_{1}}} \otimes u_{c_{r_{2}} s_{2} \omega_{r_{2}}}\right)=u_{1} \otimes u_{2}$. Set $f_{\{\leftarrow i\}}:=f_{i_{\ell}} \cdots f_{i_{1}}$. Then

$$
R\left(b_{1} \otimes b_{2}\right)=f_{\{\leftarrow i\}} e_{\{j\}}\left(u_{c_{r_{2}} s_{2} \omega_{r_{2}}} \otimes u_{c_{r_{1}} s_{1} \omega_{r_{1}}}\right) .
$$

For the case $s_{1}<s_{2}$ a similar construction works where $f_{i}$ and $e_{i}$ are interchanged.

## Acknowledgments

We thank Philip Sternberg for many stimulating discussion regarding KR crystals of type $D_{n}^{(1)}$.
